ABSTRACT: We find the marginal deformation of supersymmetric string field theory that corresponds to giving a vacuum expectation value to the photon field. We revisit the bosonic string marginal deformations and generate a real solution for it. We find a map between the solutions of bosonic and supersymmetric string field theories and suggest a universal solution to superstring field theory.

KEYWORDS: String Field Theory
1. Introduction

Our understanding of open bosonic string field theory [1] has deepened following Schnabl’s analytic solution [2], as can be seen from the papers that followed [3–14]. Specifically, marginal deformations [15–17] were found in [18, 19] and used to study the rolling tachyon in [20] (for earlier related works see [21–28]). A different approach to generate such solutions was given in [29]. The added value of the new approach is that the handling of marginal deformations that correspond to operators with a singular OPE is much easier.

For open superstring field theory [30–32] marginal deformations were found in [33–35]. The purpose of this paper is to generalize the methods of [29] to the supersymmetric theory. This gives the marginal deformation corresponding to the photon whose OPE is singular. [18, 19, 33–35].

There is a similarity between pure gauge solutions to the bosonic Chern-Simon like theory and the equation of motion of the supersymmetric WZW like theory. This similarity was recently used to generate superstring marginal deformations [33]. To adapt the method of [29] from the bosonic string to the superstring, we exploit a different similarity, one which relates the pure gauge solutions of the two theories.
The results in [29] rely on the fact that solutions of bosonic string field theory can be formally written as pure gauge solutions
\[ \Psi = \Gamma^{-1}(\Phi)Q\Gamma(\Phi), \quad (1.1) \]
where \( Q \) is the BRST charge. In the relation above, \( \Phi \) is a string field from which the solution is generated and \( \Gamma(\Phi) \) is a function of the form
\[ \Gamma(\Phi) = 1 + \Phi + O(\Phi^2), \quad (1.2) \]
where the product used is the star product and the “1” represents the identity state, which guarantees that the function \( \Gamma(\Phi) \) is invertible. The first order term generates the linear gauge transformation \( Q\Phi \).

The reason that \( \Psi \) is a physical solution has to do with the singular nature of \( \Phi \). In [29], the singularity for the photon marginal deformation was due to the linear dependence of \( \Phi \) on the zero mode \( x_0 \). In order for the solution to make sense we require that \( \Psi \) is \( x_0 \)-independent
\[ \partial_{x_0}\Psi = \partial_{x_0}(\Gamma^{-1}(\Phi)Q\Gamma(\Phi)) = 0. \quad (1.3) \]
This resembles the equation of motion of the superstring field
\[ \eta_0(G^{-1}QG) = 0, \quad (1.4) \]
where \( \eta_0 \) is the superstring ghost field zero mode, which behaves as a second BRST charge. However, this similarity is not the one we wish to exploit. Instead, we wish to compare the pure gauge solutions of both theories. In the supersymmetric theory the infinitesimal gauge transformation depends on two gauge fields \( \Lambda, \tilde{\Lambda} \)
\[ \delta G = -(Q\tilde{\Lambda})G + G(\eta_0\Lambda). \quad (1.5) \]
The integrated form of this infinitesimal gauge transformation is
\[ G_\lambda = e^{-\lambda Q\tilde{\Lambda}}G_0e^{\lambda\eta_0\Lambda}. \quad (1.6) \]
The two exponents above may be replaced by any functions of the form \([1.2]\), since this corresponds to a field redefinition. Because we are interested in pure gauge solutions, \( G_0 \) is the identity state and \( G \) is
\[ G = \tilde{\Gamma}^{-1}(\tilde{\Phi})\Gamma(\Phi), \quad \tilde{\Phi} = Q\tilde{\Lambda}, \quad \Phi = \eta_0\Lambda. \quad (1.7) \]

The gauge field \( \Phi \) of the bosonic string obviously does not have insertions of the superstring ghost field \( \xi \). Therefore, it is \( \eta_0 \)-exact and can be used to define \( \Lambda \) such that \( \Phi \) in both theories are the same
\[ \Lambda = \xi(z)\Phi_{\text{bosonic}} \quad \Rightarrow \quad \Phi_{\text{SUSY}} = \Phi_{\text{bosonic}} \equiv \Phi, \quad (1.8) \]
for any \( z \). \( \tilde{\Phi} \) can also be based on \( \Phi \) in a similar way. Here, we get a new state since \( \Phi \) is not \( Q \)-exact
\[ \tilde{\Lambda} = P(z)\Phi \quad \Rightarrow \quad \tilde{\Phi} = \Phi - P(z)Q\Phi, \quad (1.9) \]
where $P(z)$ is the inverse operator of $Q$ described in section 4.1.

A short calculation shows that the bosonic solution can be written as

$$\Psi = G^{-1} Q G. \quad (1.10)$$

Therefore it is clear that if the supersymmetric solution is $x_0$-independent then the bosonic solution follows suit

$$\partial_{x_0} G = 0 \quad \Rightarrow \quad \partial_{x_0} \Psi = 0. \quad (1.11)$$

This relation does not hold in the other direction, as the $x_0$-independence of $\Psi$ does not impose any condition on how $\Phi$ enters $G$.

The rest of the paper is organized as follows. We start in section 2 with a summary of the bosonic marginal deformation [29] and extend the formalism to generate solutions satisfying the reality condition in 2.2. Next, in section 3, we show how the relation (1.11) can be inverted, defining a map between bosonic and supersymmetric solutions. In section 4 we present the marginal deformation of the superstring. First, we show in 4.1 that the photon of the supersymmetric theory can also be written as an exact state. Then, we generate a solution to all orders in 4.2 and a real solution in 4.3. In section 5 we suggest that our method can be used to generate the universal superstring solution corresponding to Schnabl’s solution [2]. We wrap things up with conclusions in 6. In the appendices we relate our solutions to those of [33, 34].

2. Revisiting the bosonic string

2.1 Photon marginal deformation

The bosonic string marginal solution of [29] was based on the fact that the physical photon state can be written as an exact state

$$\Psi_1 = c \partial X(0) |0\rangle = Q X(0) |0\rangle. \quad (2.1)$$

This means that any pure gauge string field (1.1), which automatically satisfies the equation of motion, is a candidate solution for the photon marginal solution provided that it generates the first order state. This only requires $\Gamma(\Phi)$ to be of the form (1.2) and

$$\Phi = \lambda X(0) |0\rangle + \mathcal{O}(\lambda^2). \quad (2.2)$$

We refer to different choices of $\Gamma(\Phi)$ as “different schemes” [29]. The solution to linear order is scheme independent, and we can generate identical solutions to all orders using different schemes by modifying the higher order terms of $\Phi$.

For a solution to be meaningful, it also has to be $x_0$-independent. This can be achieved by an appropriate choice of the non-linear terms of $\Phi$. We refer to such terms as counter terms. For the “left” and “right” schemes

$$\Gamma_L(\Phi) = \frac{1}{1 - \Phi} \quad \Rightarrow \quad \Psi_L = (1 - \Phi) Q \frac{1}{1 - \Phi}, \quad (2.3)$$

$$\Gamma_R(\Phi) = 1 + \Phi \quad \Rightarrow \quad \Psi_R = \frac{1}{1 + \Phi} Q (1 + \Phi), \quad (2.4)$$

- 3 –
we have an explicit expression for the counter terms that generates such a solution. Concentrating on \( \Psi_L \), it would be \( x_0 \)-independent, provided that \( \Phi \) satisfies the linear differential equation
\[
\partial_{x_0} \Phi = \lambda (1 - \Phi) \Omega, \tag{2.5}
\]
where \( \Omega \) is the vacuum state.

It is the specific form of the function \( \Gamma_L(\Phi) \), which allows us to easily calculate derivatives despite the fact that we are working with a non-commutative algebra
\[
\partial \frac{1}{1 - \Phi} = \frac{1}{1 - \Phi} \partial \Phi \frac{1}{1 - \Phi}, \tag{2.6}
\]
where \( \partial \) can stand for any derivation. This gives
\[
\partial_{x_0} \Psi_L = - \partial_{x_0} \Phi Q \frac{1}{1 - \Phi} + (1 - \Phi)Q \left( \frac{1}{1 - \Phi} \partial_{x_0} \Phi \frac{1}{1 - \Phi} \right)
\[n\] = -\lambda (1 - \Phi) \Omega Q \frac{1}{1 - \Phi} + \lambda (1 - \Phi)Q \left( \Omega \frac{1}{1 - \Phi} \right) = 0. \tag{2.7}
\]

To solve (2.5) we expand
\[
\Phi = \sum_{n=1}^{\infty} \lambda^n \Phi_n. \tag{2.8}
\]
This reveals that the differential equation (2.5) is actually an infinite set of differential equations
\[
\partial_{x_0} \Phi_1 = \Omega, \quad \partial_{x_0} \Phi_n = -\Phi_{n-1} \Omega. \tag{2.9}
\]
Solving these linear equations order by order is straightforward, but although there are many possible solutions, we only have one solution in closed form
\[
\Phi_n = \frac{(-1)^n}{n!} (X^n, 1, \ldots, 1). \tag{2.10}
\]
Here we are using the \( n \)-vector notation to represent the wedge state \( |n + 1 \rangle \) where the vector elements represent the operator insertions at the \( n \) canonical sites of the wedge state. Normal ordering at each site is implicit and \( 1 \) stands for the identity insertion, i.e. no insertion. Actually, at each order the number of degrees of freedom for generating a solution is
\[
\text{dim}(\Phi_n) = \binom{2n - 2}{n}. \tag{2.11}
\]
These degrees of freedom are in general complex. They correspond to the number of gauge degrees of freedom within our ansatz.

### 2.2 The reality condition

Next we would like to find a solution that satisfies the string field reality condition. The reality condition states that hermitian conjugation and BPZ conjugation agree. In our vector notation the reality condition translates to the following statement. Write the state in the opposite orientation, with a factor of \((-1)\) for every \( X \) or \( \partial c \) insertion and no factors
for $\partial X$ and $c$ and complex conjugate the coefficients. If this procedure returns the original state then the state is real. For simplicity, we consider only real coefficients (and real $\lambda$), as it turns out that this is sufficient for constructing a real string field. In particular the function $\Gamma(\Phi)$ of (1.1) will always be a real function.

Since $\Phi$ is built only from $X$ insertions, its reality is simply related to its symmetry. The component of $\Phi_n$ is imaginary provided it is symmetric under inversion when $n$ is odd and antisymmetric when $n$ is even. To evaluate the number of degrees of freedom we consider the space of solutions of the homogeneous equation

$$\partial_{x_0} \Phi_n = 0.$$  \hfill (2.12)

The space of solutions of this equation is given by the quotient of the space of homogeneous polynomials of degree $n$ in $n$ variables by the space of homogeneous polynomials of degree $n-1$ in $n$ variables. The dimension of this space is given by (2.11). We now divide both spaces into symmetric and antisymmetric parts. The derivative $\partial_{x_0}$ does not change the symmetry property and, as we shall soon demonstrate, it is also possible to define integration in a way that respects the symmetry. Hence, the number of (anti-)symmetric degrees of freedom is just the dimension of the quotient space of the two (anti-)symmetric spaces. The combinatorics is different for the cases of $n$ odd/even. The result can be summarized by

$$\dim(\Phi_n^{S,A}) = \frac{1}{2} \left( \binom{2n-2}{n} \pm \frac{(-1)^n}{2} \binom{n-1}{\frac{n}{2}} \right), \hfill (2.13)$$

where the plus sign stands for the symmetric case.

We have only two solutions in a closed form, the one described above in the left-scheme and a corresponding solution in the right-scheme. It is clear that these solutions are not real since they have no symmetry. We can, however, generate different solutions. Let us work in the left-scheme. At level two, imposing the reality condition, and using only real coefficients the unique solution is

$$\Phi_2 = -\frac{1}{4} ((X^2, 1) + 2(X, X) - (1, X^2)). \hfill (2.14)$$

At level three there are two degrees of freedom for choosing a real solution.

Already in the expression for the counter terms at level two we have the term $(X, X)$, which we interpret as ‘changing the scheme’ [29]. Thus, it may seem beneficial to start with a scheme where the symmetry is more transparent. We want a systematic procedure for generating real solutions. From

$$\Psi^* = \Gamma(\Phi^*)Q\Gamma^{-1}(\Phi^*), \hfill (2.15)$$

we see that the reality condition can be written as$^1$

$$\Gamma(\Phi) = \Gamma^{-1}(\Phi^*). \hfill (2.16)$$

$^1$Expanding $\Gamma(\Phi)$ in $\lambda$, this condition fixes the real part of the $n^{th}$ order in term of the lower orders.
This condition is generically non-linear in $\Phi, \Phi^*$. However for schemes of the form

$$\Gamma(\Phi) = \Gamma^{-1}(-\Phi),$$

(2.17)

we get the linear reality condition

$$\Phi^* = -\Phi.$$  

(2.18)

It is indeed natural to require that $\Phi$ is imaginary since $\Phi_1$ is imaginary.

The three other schemes that were specifically considered in [29], i.e., the symmetric scheme, the exponent scheme and the square root scheme, are given by

$$\Gamma_S(\Phi) = \frac{1 + \Phi}{1 - \Phi^2}, \quad \Gamma_E(\Phi) = e^\Phi, \quad \Gamma_R(\Phi) = \sqrt{\frac{1 + \Phi}{1 - \Phi}}.$$  

(2.19)

For the symmetric scheme we can use the algebraic relation between the two $\Phi$’s to obtain a differential equation analog of (2.5),

$$\partial_{x_0} \Phi = \lambda (1 - \Phi^2) \Omega(1 + \Phi^2).$$  

(2.20)

Note that this equation is invariant under conjugation (2.18), since the conjugate of $\partial_{x_0}$ is $-\partial_{x_0}$. This yields a recursion relation for $\Phi_k$,

$$\partial_{x_0} \Phi_k = \frac{1}{2} \Omega \Phi_{k-1} - \frac{1}{2} \Phi_{k-1} \Omega - \frac{1}{4} \sum_{j=1}^{k-2} \Phi_j \Omega \Phi_{k-1-j}.$$  

(2.21)

In order to prove that real solutions exist within our ansatz we provide an explicit integration recipe that is manifestly imaginary. This not only proves that a real solution exists, but also gives an easy algorithm to find it order by order. Unfortunately, we have not yet found a closed form expression for the real solution.

Given a site $k$, one can define the integration “localized at this site” of a length-$n$ vector by

$$\int_k(X^{j_1}, \ldots, X^{j_k}, \ldots, X^{j_n}) \equiv \frac{1}{jk + 1} (X^{j_1}, \ldots, X^{j_k+1}, \ldots, X^{j_n})$$

$$- \frac{1}{(jk + 1)(jk + 2)} \sum_{m \neq k} \partial_{X_m} (X^{j_1}, \ldots, X^{j_k+2}, \ldots, X^{j_n})$$

$$+ \frac{1}{(jk + 1)(jk + 2)(jk + 3)} \sum_{m_1 \neq k} \sum_{m_2 \neq k} \partial_{X_{m_1}} \partial_{X_{m_2}} (X^{j_1}, \ldots, X^{j_k+2}, \ldots, X^{j_n}) \ldots$$

(2.22)

The number of terms is finite, since the total power is finite. What we are doing is basically an integration by parts, such that the power at the $k^{th}$ site is raised, while the power at other sites is reduced.

Since the power of $X$ is always raised by one in the integration, the combination $\int_k + \int_{n-k}$ is odd. The integration operations are linear and so any combination of the form

$$\int_{\vec{\alpha}} \equiv \sum_{k=1}^{n} \alpha_k^k \int_k, \quad \sum_{k=1}^{n} \alpha_n^k = 1,$$

(2.23)
yields an integral. Thus, an integration scheme that involves a symmetric choice of \( \vec{\alpha}_n \) is well defined and imaginary. Integrating \( \{2.21\} \) with any such scheme gives a solution that is imaginary by construction. For example, the choice \( \alpha_1^1 = \alpha_n^n = \frac{1}{n} \) gives at the first few orders

\[
\Phi_1 = (X),
\]
\[
\Phi_2 = \frac{1}{4} \left( (1, X^2) - (X^2, 1) \right),
\]
\[
\Phi_3 = \frac{1}{48} \left( (X^3, 1, 1) + 6(X^2, X, 1) - 3(X^2, 1, X) - 6(X, X^2, 1)
- 3(X, X^2) - 6(1, X^2, X) + 6(1, X, X^2) + (1, 1, X^3) \right),
\]

while another choice is \( \alpha_1^k = \frac{1}{n} \), which differs starting from the third order

\[
\Phi_3 = \frac{1}{72} \left( (X^3, 1, 1) + 9(X^2, X, 1) - 3(X^2, 1, X) - 6(X, X^2, 1) - 6(X, X, X)
- 3(X, X^2) - 2(1, X^3, 1) - 6(1, X^2, X) + 9(1, X, X^2) + (1, 1, X^3) \right).
\]

The first choice seems more natural since it does not involve the scheme changing state \( (X, X, X) \). Yet another symmetric integration scheme is to integrate each term of \( \{2.21\} \) at the \( \Omega \)-site.

3. A map between bosonic and supersymmetric solutions

In the introduction we saw how an \( x_0 \)-independent solution for the bosonic string can be built from an \( x_0 \)-independent solution of the superstring \( \{1.10, 1.11\} \). To understand how this procedure works in the other direction it is useful to define

\[
\Xi_\Gamma(x_0) \equiv (\partial_{x_0} \Gamma) \Gamma^{-1}.
\]

It is interesting to observe that \( \Gamma \) is the path-ordered exponential of \( \Xi_\Gamma \)

\[
\Gamma = \mathcal{P} \exp \int_{x_0}^x \Xi_\Gamma(x)dx = 1 + \sum_{n=1}^{\infty} \int_{x_0}^{x_1} \Xi_\Gamma(x_1)dx_1 \int_{x_1}^{x_2} \Xi_\Gamma(x_2)dx_2 \cdots \int_{x_{n-1}}^{x_n} \Xi_\Gamma(x_n)dx_n.
\]

The freedom in defining the above integration goes beyond setting lower limits to the integrals, as \( x_0 \) can be related to \( X(z) \) insertions at any point on the boundary, giving a continuum of degrees of freedom. Restricting the resulting expressions to the form of our ansatz, leaves us with the same expressions for \( \Gamma \) and the same ambiguity of defining the integration scheme discussed in the previous section. A similar construction was used in [35] to generate a real solutions from a real \( \Xi \). The difference is that in [35], one integrates over the gauge parameter \( \lambda \) rather than over \( x_0 \).

Our main observation here, is that the condition for \( x_0 \)-independence of \( \Psi \) is equivalent to the condition that \( \Xi_\Gamma \) is \( Q \)-closed, since

\[
\partial_{x_0} \Psi = \Gamma^{-1} (Q \Xi_\Gamma) \Gamma,
\]
which follows from the definition of $\Psi$ in (1.1).

For a supersymmetric solution of the form (1.7), we can write

$$\partial_{x_0} G = \tilde{\Gamma}^{-1}(\Xi \Gamma - \Xi \tilde{\Gamma}) \Gamma.$$  

(3.4)

Thus, $x_0$-independence is equivalent to the condition

$$\Xi \tilde{\Gamma} = \Xi \Gamma.$$  

(3.5)

Now, since $\tilde{\Phi}$ is exact

$$Q \tilde{\Phi} = 0 \Rightarrow Q \tilde{\Gamma} = 0 \Rightarrow Q \Xi \tilde{\Gamma} = Q \Xi \Gamma = 0.$$  

(3.6)

We see that $x_0$-independence of $G$ implies that $\Xi \Gamma$ is closed. This proves (1.11) with the new definitions.

The differential equations of the bosonic solutions in the left, right and symmetric schemes, all result in the scheme independent expression

$$\Xi \Gamma = -\lambda \Omega.$$  

(3.7)

This relation is not modified if we replace $\Phi$ by $\tilde{\Phi}$. Therefore, all schemes can be used interchangeably to create supersymmetric solutions.

4. Supersymmetric marginal deformations

It is not a priori clear to which superstring state the bosonic photon marginal deformation would be mapped. First, in 4.1 we show that the photon state of the supersymmetric theory can be written as a pure gauge state. This proves that the full superstring photon marginal deformation can be generated using our methods. Then, we demonstrate how to get explicit solutions to all orders in 4.2 and real solutions in 4.3.

4.1 The linear solution

Expanding the superstring field

$$G = 1 + \lambda G_1 + \mathcal{O}(\lambda^2),$$  

(4.1)

yields the linear order of the superstring field equation of motion (1.4)

$$\eta_0 Q G_1 = 0.$$  

(4.2)

The photon state

$$G_1 = c \xi e^{-\phi} \psi(0) |0\rangle,$$  

(4.3)

solves this equation. Here, $\psi$ has an implicit $\mu$ index and is of conformal weight $\frac{1}{2}$. Like in the bosonic case, we would like to write this state as a pure gauge state generated by a singular gauge transformation. This will allow us to generate the higher order terms for this solution. In superstring field theory there are two gauge fields from which pure gauge
states can be built. Expanding the infinitesimal gauge transformation \((1.5)\) to linear order in \(\lambda\) gives

\[
G_1 = -Q\tilde{\Lambda}_1 + \eta_0\Lambda_1 .
\]

(4.4)

Notice that \(G_1\) has the \(\xi_0\) operator in it, implying that it lies in the large Hilbert space.

An important property of the large Hilbert space is that the BRST charge

\[
Q = \oint dz J_B(z) = \oint dz \left( c(T_m + T_{\xi\eta} + T_{\phi}) + c\partial cb + \eta e^\phi G_m - \eta\partial\eta e^{2\phi}b \right) ,
\]

(4.5)

has an inverse in this space

\[
\{Q, P(z)\} = 1, \quad P(z) \equiv -\xi\partial\xi e^{-2\phi}c(z) .
\]

(4.6)

To verify this we use the following identities

\[
T_{\xi\eta} = -\eta\partial\xi , \quad \eta\xi \sim \frac{1}{z} , \quad T_{\phi} = -\frac{1}{2}\partial\phi\partial\phi - \partial^2\phi , \quad \phi\phi \sim -\log z , \quad \phi e^{\eta\phi} \sim -q\log z e^{\eta\phi} , \quad e^{q_1\phi(z)}e^{q_2\phi(0)} = z^{-q_1q_2}e^{q_1\phi(z)+q_2\phi(0)} .
\]

(4.7)

The conformal weight \(h\), ghost number \(n_g\) and picture number \(n_p\) of the operators we work with are listed below:

| operator \( | \) | \( h \) \( | \) \( n_g \) \( | \) \( n_p \) |
|---|---|---|---|
| \( b \) \( | \) | 2 \( | \) -1 \( | \) 0 |
| \( c \) \( | \) | -1 \( | \) 1 \( | \) 0 |
| \( \eta \) \( | \) | 1 \( | \) 1 \( | \) -1 |
| \( \xi \) \( | \) | 0 \( | \) -1 \( | \) 1 |
| \( e^{\eta\phi} \) \( | \) | \( -q(q+2) \) \( | \) 0 \( | \) \( q \) |
| \( \beta = \partial\xi e^{-\phi} \) \( | \) | \( \frac{3}{2} \) \( | \) -1 \( | \) 0 |
| \( \gamma = \eta e^\phi \) \( | \) | \( -\frac{1}{2} \) \( | \) 1 \( | \) 0 |
| \( J_B \) \( | \) | 1 \( | \) 1 \( | \) 0 |
| \( P \) \( | \) | 0 \( | \) -1 \( | \) 0 |

(4.9)

Some other useful identities include

\[
Q^2 = P^2(z) = \eta_0^2 = \xi^2(z) = \{Q, \eta_0\} = 0 , \quad \{\eta_0, \xi(z)\} = 1 .
\]

(4.10)

These relations reveal a duality under exchange of \(Q\) with \(\eta_0\) and \(P(z)\) with \(\xi(z)\).

Like in the bosonic case we have to enlarge the Hilbert space using \(x_0\). The \(\psi\) operator will be generated thanks to the \(\gamma G_m\) factor in the BRST charge\(^2\)

\[
G_m = i\sqrt{2}\psi\partial X \Rightarrow [Q, X] = c\partial X - i\sqrt{2}\eta e^\phi\psi .
\]

(4.11)

Then it is natural to guess

\[
\tilde{\Lambda}_1 = PX(0) |0\rangle \Rightarrow \tilde{\Phi}_1 = Q\tilde{\Lambda}_1 = X(0) |0\rangle - PQX(0) |0\rangle .
\]

(4.12)

\(^2\)Note that we use the conventions of [29] for \(\partial X\) on the boundary. This differs by a factor of 2 from the one in \(G_m\).
The first term is redundant and can be canceled by the other gauge field
\[ \Lambda_1 = \xi X(0) |0\rangle \Rightarrow \Phi_1 = \eta_0 \Lambda_1 = X(0) |0\rangle . \quad (4.13) \]

In total we get
\[ G_1 = -\tilde{\Phi}_1 + \Phi_1 = PQX(0) |0\rangle = P(c\partial X - i\sqrt{2}\eta e^{\phi}\psi)(0) |0\rangle = c\xi e^{-\phi} \psi(0) |0\rangle , \quad (4.14) \]
which is exactly what we want.

### 4.2 Higher order terms

To get a solution to the non-linear equation of motion we need to use the integrated gauge transformation (1.7). Plugging the first order gauge parameters (4.12), (4.13) into (1.7) produces \( x_0 \)-dependence at higher orders, no matter what functions \( \Gamma(\Phi), \tilde{\Gamma}(\tilde{\Phi}) \) are used. We therefore need to add counter terms.

We choose to work in the left scheme, for which we have a closed form solution in the bosonic theory. Relying on the relation between the bosonic and supersymmetric solutions we write \( G_L \) in a form similar to \( \Psi_L \)
\[ G_L = \Gamma^{-1}_L(\tilde{\Phi}) \Gamma_L(\Phi) = (1 - \tilde{\Phi}) \frac{1}{1 - \Phi} , \quad (4.15) \]
and assume that both \( \Phi \) and \( \tilde{\Phi} \) satisfy equations similar to the bosonic case
\[ \partial_{x_0} \Phi = \lambda (1 - \Phi) \Omega , \quad \partial_{x_0} \tilde{\Phi} = \lambda (1 - \tilde{\Phi}) \Omega . \quad (4.16) \]

Not surprisingly, this gives an \( x_0 \)-independent solution
\[ \partial_{x_0} G_L = 0 . \quad (4.17) \]

It is insufficient to solve (4.16) since these equations are not for the gauge fields. We therefore need to write similar equations for the gauge fields
\[ \partial_{x_0} \Lambda = \lambda (\xi(0) \Omega - \Lambda \Omega) , \quad \partial_{x_0} \tilde{\Lambda} = \lambda (P(0) \Omega - \tilde{\Lambda} \Omega) , \quad (4.18) \]
from which (4.16) directly follow. The position of the \( P \) and \( \xi \) operators was explicitly shown to emphasize that they operate on the vacuum state and not star-multiply it. The solution for the gauge fields is
\[ \Lambda = \sum_{n=1}^{\infty} \lambda^n \Lambda_n , \quad \Lambda_n = -\frac{(-1)^n}{n!}(\xi X^n, \ldots , 1) , \quad (4.19) \]
\[ \tilde{\Lambda} = \sum_{n=1}^{\infty} \lambda^n \tilde{\Lambda}_n , \quad \tilde{\Lambda}_n = -\frac{(-1)^n}{n!}(PX^n, \ldots , 1) , \quad (4.20) \]
which yields the string fields
\[ \Phi = \eta_0 \Lambda = -\sum \frac{(-1)^n}{n!}(X^n, \ldots , 1) , \quad (4.21) \]
\[ \tilde{\Phi} = Q \tilde{\Lambda} = -\sum \frac{(-1)^n}{n!}(X^n - nYX^{n-1} - n(n-1)ZX^{n-2}, \ldots , 1) . \quad (4.22) \]
For this calculation we have used the commutation relation
\[ [Q, X^n] = -i\sqrt{2} n \eta e^\phi \psi X^{n-1} + n c \partial X X^{n-1} - n(n-1) \partial c X^{n-2}, \]  
and defined
\[ Y \equiv -i\sqrt{2} P \eta e^\phi \psi = -i\sqrt{2} c \xi e^{-\phi} \psi, \quad Z \equiv c \partial c \xi e^{-2\phi}. \]  
The operator \( Z \) has the unique property that all its quantum numbers are zero.

As mentioned in the introduction, the field \( \Phi \) of the superstring looks exactly the same as the field \( \Phi \) of the bosonic string. The fact that \( \Phi \) is \( \eta_0 \) closed means that the related gauge transformation can be simply written as
\[ \Lambda = \xi_0 \Phi. \]  
This state does not obey (4.18), but it only differs from (4.19) by an \( \eta_0 \)-closed term. Thus, both states are legitimate.

### 4.3 Real solutions

We now want to identify a real solution. The reality condition for the superstring field is
\[ G^\dagger = G^{-1}. \]  
The fields \( X \) and \( Y \) are imaginary and \( Z \) is real. We assume that \( \Phi \) and \( \tilde{\Phi} \) are chosen such that they keep the imaginary nature of their lowest order. Then for \( G \) to be real, the functions that generate it need to satisfy (2.17) just as in the bosonic case. The next step is to imitate the bosonic symmetric solution
\[ G = \Gamma_S^{-1}(\tilde{\Phi}) \Gamma_S(\Phi) = \frac{1 - \frac{1}{2} \tilde{\Phi}}{1 + \frac{1}{2} \Phi} \left( 1 + \frac{1}{2} \Phi \right), \]  
and require
\[ \partial_{x_0} \Phi = \lambda \left( 1 - \frac{1}{2} \Phi \right) \Omega(1 + \frac{1}{2} \Phi), \quad \partial_{x_0} \tilde{\Phi} = \lambda \left( 1 - \frac{1}{2} \tilde{\Phi} \right) \Omega(1 + \frac{1}{2} \tilde{\Phi}), \]  
to get an \( x_0 \)-independent solution. Just like in the left scheme solution, the expression for the supersymmetric \( \Phi \) is the same as that of \( \Phi \) of the bosonic string. For \( \tilde{\Phi} \) we need to solve the equation
\[ \partial_{x_0} \tilde{\Lambda} = \lambda \left( P(0) \Omega - \frac{1}{2} \tilde{\Lambda} \Omega + \frac{1}{2} \Omega \tilde{\Lambda} - \frac{1}{8} \tilde{\Lambda} \Omega (Q \tilde{\Lambda}) - \frac{1}{8} (Q \tilde{\Lambda}) \Omega \tilde{\Lambda} \right), \]  
where we have chosen the symmetric form of the equation. We can use the integration choices from the bosonic string, but they result in unnatural looking expressions. Instead we choose to integrate only over locations with a \( P \) insertion. The second order result is then
\[ \tilde{\Phi}_2 = \frac{1}{4} \left( (1, X^2 - 2XY - 2Z) - \left( X^2 - 2XY - 2Z, 1 \right) \right), \]  
\[ G_2 = \frac{1}{2} \left( (1, XY) - (XY, 1) + (Y, X) - (X, Y) + (Y, Y) - (Z, 1) + (1, Z) \right), \]  
where we have taken the expression for \( \Phi_2 \) from the bosonic string.
5. The universal superstring solution

Schnabl’s original solution for the bosonic string [2] can also be written as a gauge transformation [3]

$$\Psi_\lambda = (1 - \lambda \Phi) \frac{1}{1 - \lambda \Phi}, \quad \Phi = \frac{1}{\pi} B_0^1 c(0) |0\rangle. \quad (5.1)$$

$\Phi$ may also be viewed as a singular gauge transformation since it generates a field which is both exact and satisfies the Schnabl gauge

$$B_0 Q \Phi = 0. \quad (5.2)$$

The Siegel gauge does not seem to permit such states.

Let us define a similarity transformation like the one we used for regularizing the three-vertex [9]

$$B_0^s \equiv s^{-L_0} B_0 s^{L_0}, \quad \Phi_s \equiv s^{-L_0} \Phi. \quad (5.3)$$

For any finite $s$, states in the Schnabl gauge transform into states in the $B_0^s$ gauge. In the limit $s \to 0$ we reach the Siegel gauge. All physical states transform from the Schnabl gauge to the Siegel gauge, but the state $\Phi$ is singular in this limit, due to the singularity in this limit of $B_0^1$ (and $L_0^1$).

A conceptual difference between Schnabl’s universal solution and our marginal deformation is that for small $\lambda$ his solution is indeed a pure gauge solution. Only at the critical value $\lambda = 1$ does it become a physical solution. Still, we can speculate that the relation between bosonic and superstring solutions also holds for this case. The state

$$G_\lambda = (1 - \lambda \tilde{\Phi}) \frac{1}{1 - \lambda \tilde{\Phi}}, \quad \tilde{\Phi} = Q P(0) \Phi. \quad (5.4)$$

is clearly a solution to the superstring field equation of motion. $\Phi$ was copied from the bosonic string and since it is built upon the vacuum state, there seems to be no ambiguity about the location of the $P$ insertion in $\tilde{\Phi}$. One can check that $G_\lambda$ satisfies Schnabl’s gauge

$$B_0 (G_\lambda - 1) = 0. \quad (5.5)$$

We suggest that at the critical value of $\lambda$ this could be the universal solution for the superstring. Generically, there is no tachyon in superstring field theory, so we should not think of this state as being the tachyon vacuum. We believe that this solution represents a state with no $D$-branes and therefore has an empty cohomology.

Like in the bosonic case, the study of this state should require some kind of regularization. We leave this study for future work.

6. Conclusions

It seems that all known solutions to bosonic and supersymmetric string field theories can be written as pure gauge solutions. The difference between different solutions and different approaches is in the choice of the gauge field. The approach of this paper and [29] gives elegant results that generalize automatically to singular currents, but works only for the
photon operator. The approach of \cite{18, 19, 33–35} works for all non-singular currents, but requires complicated counter terms for handling singular currents. The generalization of our approach to other operators was discussed in \cite{29}. It would be interesting to complete this program.

Acknowledgments

We would like to thank Sudarshan Ananth, Rob Potting and Stefan Theisen for useful discussions. The work of M. K. is supported by a Minerva fellowship. The work of E. F. is supported by the German-Israeli Project cooperation (DIP H.52).

A. Split string formalism

In order to compare our solution to that obtained by other authors it may be useful to write it using the formalism of \cite{33}. Insertion of $X^n$ will be described by an insertion over the identity string field,

$$X^n \equiv X^n |1\rangle = X \ast \ldots \ast X \text{\ n times}. \tag{A.1}$$

Normal ordering in this expression is implicit, therefore the r.h.s. cannot be strictly viewed as a chain of matrix multiplications.

Then, between any two insertion sites there is a strip of string that can be represented by $F_2 = \Omega$. For example, the bosonic left solution is given by

$$1 - \Phi = 1 + F \sum_{k=1}^{\infty} \frac{(-\lambda)^k}{k!} X^k F^{2k-1} \equiv F \sum_{k=0}^{\infty} \frac{(-\lambda)^k}{k!} X^k F^{2k-1}. \tag{A.2}$$

This can be written in short as

$$1 - \Phi = F e^{\partial_\alpha \partial_\beta} e^{-\alpha \lambda X} e^{\beta \Omega} \bigg|_{\alpha=\beta=0} F^{-1}. \tag{A.3}$$

Using the bosonic part of \cite{4,23} we can write the solution as

$$\Psi = \lambda F c \partial X F^{-1} (1 - \Phi) \Omega (1 - \Phi)^{-1} + \lambda^2 F \partial c F^{-1} (1 - \Phi) \Omega^2 (1 - \Phi)^{-1}. \tag{A.4}$$

B. Integrated strip formalism

The marginal deformations in \cite{18,19,34,35} were all based on the fact that the inverse of $L_0$ can be written as an integration over the width of a strip of string. Here, we demonstrate that these solution can also be viewed as pure gauge solutions.

For the bosonic string, our solution is based on the fact that $\Psi_1$, which is closed

$$Q \Psi_1 = 0, \tag{B.1}$$

can be written as an exact state

$$\Psi_1 = Q \Phi_1. \tag{B.2}$$
Using the integrated strip one can define the state $J$, which satisfies

$$QJ = 1. \quad (B.3)$$

We can use this state to write

$$\Phi_1 = J\Psi_1 \Rightarrow Q\Phi_1 = (QJ)\Psi_1 - J(Q\Psi_1) = \Psi_1, \quad (B.4)$$

which is exactly what we need. Then the full solution, ignoring the issue of singular OPE’s is

$$\Psi_n = (Q\Phi_1)\Phi_1^{n-1} = \Psi_1(J\Psi_1)^{n-1}. \quad (B.5)$$

This is exactly the form of the solution of [34]. The structure of this solution is exactly like ours, yet the states involved are different. Specifically,

$$X(0)|0\rangle \neq J\partial X(0)|0\rangle. \quad (B.6)$$

The supersymmetric theory requires a different $J$ state. This time $J$ satisfies the relation

$$Q\eta_0 J = 1. \quad (B.7)$$

We can use this state to write

$$\Lambda = \lambda (QG_1)J \Rightarrow \Phi = \eta_0 \Lambda = -\lambda (QG_1)(\eta_0 J), \quad (B.8)$$

$$\bar{\Lambda} = -\lambda G_1(\eta_0 J) \Rightarrow \bar{\Phi} = Q\bar{\Lambda} = -\lambda G_1 - \lambda (QG_1)(\eta_0 J), \quad (B.9)$$

where we used (4.2). This means that every state of the form

$$G = \tilde{\Gamma}^{-1}(\bar{\Phi})\Gamma(\Phi), \quad (B.10)$$

solves the equation of motion, with the right linear term $G_1$, if the functions $\Gamma, \tilde{\Gamma}$ are of the form (1.2). The superstring marginal solution of [34]

$$G^{-1} = 1 - \frac{\lambda}{1 - \lambda (QG_1)(\eta_0 J)}G_1, \quad (B.11)$$

can be reproduced by choosing

$$\Gamma(\Phi) = 1 + \Phi, \quad \tilde{\Gamma}(\bar{\Phi}) = 1 + \bar{\Phi}. \quad (B.12)$$
