Abstract

We study global existence problems and asymptotic behavior of higher-dimensional inhomogeneous spacetimes with a compact Cauchy surface in the Einstein-Maxwell-dilaton (EMD) system. Spacelike $T^{D-2}$-symmetry is assumed, where $D \geq 4$ is spacetime dimension. The system of the evolution equations of the EMD equations in the areal time coordinate is reduced to a wave map system, and a global existence theorem for the system is shown. As a corollary of this theorem, a global existence theorem in the constant mean curvature time coordinate is obtained. Finally, for vacuum Einstein gravity in arbitrary dimension, we show existence theorems of asymptotically velocity-terms dominated singularities in the both cases which free functions are analytic and smooth.

1 Introduction and summary

Global existence problems of fundamental field equations must be solved as the first step of the strong cosmic censorship, which states that generic Cauchy data sets have maximal Cauchy developments which are locally inextendible as Lorentzian manifolds. It is important to consider the strong cosmic censorship in scope of unified theories such that superstring/M-theory. As is well known, such unified theories predict that the spacetime dimension exceeds four and it is expected that such extra dimensions must not be different from ordinary dimensions and should be taken into account in the asymptotic regions (e.g. near the singularities) of spacetimes. Although higher-dimensional model have a long history within superstring/M-theory, mathematically rigorous results for cosmological spacetimes are much less understood than for stationary ones (for examples, see [GSW]). In particular, there has been less exploration of global in time problems in higher-dimensional, cosmological spacetimes. Recently, spatially homogeneous cosmological models was analyzed [HS]. Then, we want to study an inhomogeneous cosmological case as the next step.

In the cosmological context, it seems convenient to consider spacetimes which develop from smooth Cauchy data given on a compact, connected and orientable Cauchy hypersurface. In addition, we would like to investigate inhomogeneous cosmological spacetimes with dynamical degree of freedom of gravity. Then, we will consider globally hyperbolic spacetimes $(M_D, g)$, with $M_D = M_{D-1} \times \mathbb{R}$ a smooth $D$-dimensional manifold ($D \geq 4$), $g$ a Lorentzian metric, which develop from smooth Cauchy data invariant under an effective action of $G_{D-2} = U(1) \times U(1) \times \cdots \times U(1) = T^{D-2}$ on a compact $(D-1)$-dimensional spacelike manifold $M_{D-1}$. The same symmetry is assumed for matter fields if they exist. The resulting system of field equations becomes one of 1+1 nonlinear partial differential equations (PDEs). From Mostert’s theorem [MP] it is admitted that $M_{D-1}/G_{D-2}$ is a circle and $M_{D-1}$ is homeomorphic to $S^1 \times T^{D-2} = T^{D-1}$. Therefore, we will suppose $M_{D-1} \approx T^{D-1}$.

In four-dimensional vacuum spacetimes with the above setting, Moncrief and Isenberg have proved global existence theorems of the Einstein equations in areal and constant mean curvature time coordinates [MV, IM]. Recently, it has been generalized to non-vacuum case [AH, ARW, HO, NM02, NM03]. One purpose of the present paper is to extend the previous results to higher-dimensional spacetimes.

Once it has been shown global existence theorems, we want to know asymptotic behavior of cosmological spacetimes as the next step. That is, it should be analyzed nature of spacetime regions near
singularity (if incomplete) and near infinity (if complete). In this paper, we will focus to consider nature of singularities. It is conjectured that, near a cosmological singularity, a decoupling of spatial points occurs in the sense that evolution equations cease to be PDEs to simply become, at each spatial point asymptotically, ordinary differential equations with respect to time [BKL]. In other words, cosmological singularities are locally asymptotically velocity-terms dominated (AVTD \textsuperscript{1}) or mixmaster. Concerning this BKL conjecture, it has been shown that four-dimensional Gowdy symmetric spacetimes with or without stringy matter fields (with dilaton couplings) have AVTD singularities in general in the sense that the singular solutions depend on the maximal number of arbitrary functions [KR, NTM]. These results have been made no-symmetric and higher-dimensional generalization [DHRW]. That paper has established AVTD behavior for vacuum gravity in spacetime dimension $D > 10$ and for the Einstein-dilaton-matter system with dilaton couplings in spacetime dimension $D \geq 2$. Thus, the question whether the AVTD behavior exists or not still remains open for vacuum Einstein gravity in dimensions $D \in [5, 10]$ rigorously.

Another purpose of the present paper is to show that there is AVTD behavior for vacuum Einstein gravity in arbitrary spacetime dimension. This result complements the BKL conjecture by combining together the previous works mentioned above.

The above results concerning AVTD behavior are of $C^\omega$ (analytic) category. Recently, it has been extended to $C^\infty$ (smooth) category in the case of four-dimensional vacuum Gowdy spacetimes with any spatial topology [RA, SF]. We will generalize this to higher-dimensional spacetimes and tie the result on AVTD singularities together with the global existence results.

Let us consider a truncated action of the bosonic supergravity theory (i.e. low energy effective superstring/M-theory), which contains only the gravitational (metric), the dilaton and $p$-form fields. It can be shown that this truncation is consistent, in the sense that the fields that are retained are not sources for the fields that are eliminated [SK]. In this paper, we will consider the case $p = 1$. Thus, the system becomes the Einstein-Maxwell-dilaton (EMD) system. The action for the $D$-dimensional EMD system is given by

$$S_D = \int d^D x \sqrt{-\text{det} g} \left[ -D R + 2(\partial \phi)^2 + e^{-2\phi} F^2 \right],$$

where $D R$ is the Ricci scalar with respect to $g$, $\phi$ is the dilaton field, $F_{\mu \nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the Maxwell field strength and $a$ is a coupling constant. Varying the action we have the following field equations:

$$D R_{\mu \nu} + 2 \partial_\mu \phi \partial_\nu \phi + e^{-2\phi} \left[ 2g^{\lambda \sigma} F_{\mu \lambda} F_{\nu \sigma} - \frac{1}{D-2} g_{\mu \nu} F^2 \right],$$

$$D \Box \phi + \frac{a \chi}{2} e^{-2a \phi} F^2 = 0,$$

$$\partial_\mu (\sqrt{-\text{det} g} e^{-2\phi} F_{\mu \nu}) = 0$$

and

$$\partial_\mu F_{\nu \lambda} = 0,$$

where $\mu$, $\nu$, $\lambda$ run from 0 to $D - 1$, $D R_{\mu \nu}$ and $D \Box$ are the Ricci tensor and the d’Alembertian with respect to $g_{\mu \nu}$, respectively. Note that truncation of the Maxwell fields or of both the Maxwell and the dilaton fields is consistent, but trivializing only the dilaton field does not induce the Einstein-Maxwell (EM) system from the EMD system. In this case, as we can see from the dilaton equation (3), the EM system with a constraint $F^2 = 0$ would be obtained.

2 \textit{G}_{D-3}\text{-invariant spacetimes: Reduction of a wave map system coupled to three-dimensional gravity}

We take $M_{D-1}$ to be a principal fiber bundle with compact, two-dimensional base $\Sigma$, with fibers the orbits of $G_{D-3} = U(1) \times \cdots \times U(1) = T^{D-3}$, and with a metric $g$ on $M_D$ invariant under the right action of $G_{D-3}$. Therefore, $M_{D}$ is a principal fiber bundle with base $\Sigma \times \mathbb{R}$ and group $G_{D-3}$.

\textsuperscript{1}In this article, the word “AVTD behavior” is equivalent to “Kasner-like behavior”.

Let $\xi_I = \partial_I$ ($I = 3, \cdots, D - 1$) be $(D - 3)$ spacelike commuting Killing vector fields, such that $\mathcal{L}_{\xi_I} g = 0$ and $[\xi_I, \xi_J] = 0$. Note that the Killing vectors are tangent to $\mathcal{M}_{D - 1}$, hence spacelike. Form the hypotheses, the metric $g$ for the spacetime is [CBDWM]

$$g = f^{-1}\gamma_{mn} dx^m dx^n + f_{IJ} \Theta^I \Theta^J, \quad \Theta^I := dx^I + W^I_m dx^m,$$

where $f^{-1}\gamma_{mn}$ is a metric on $\Sigma \times \mathbb{R}$, $m, n, i, j = 0, 1, 2$, $f = \det f_{IJ} > 0$. $\gamma_{mn}$, $W^I_m$ and $f_{IJ}$ are depend only on the coordinates $x^m$, that is a necessary and sufficient condition for the metric $g$ to be invariant under the right action of $G_{D - 3}$.

We consider the Maxwell field $A_\mu$. Assume that there is a gauge such that the $U(1)$ gauge field respects the spacetime symmetry $\mathcal{L}_{\xi_I} A = 0$. Then we have $\partial_I A_\mu = 0$. According to [IW] (see also [IU]), we can define the Maxwell field potentials $\Phi_I$ and $\Psi$ from equations (5) and (4) as follows.

$$F_{\mu I} = \partial_\mu \Phi_I, \quad e^{-2a\phi} F^{mn} = \frac{2f}{\sqrt{-\det \gamma}} \epsilon^{mnp} \partial_\mu \Psi,$$

where $\epsilon_{mnp}$ denotes the permutation symbol such that $\epsilon_{012} = 1$ and $\epsilon_{mn0} = 0$. The equation (7) satisfies a part of the Bianchi identity (5), while the equation (8) fulfills a part of the Maxwell equations (4). From (7) and (8) the remaining Maxwell equations and the Bianchi identity can be described through $\Phi_I, \Psi, f_{IJ}, W^I_m$ and $\gamma_{mn}$. Introduce torsion defined by

$$\omega_{I\mu} = \sqrt{-\det g} \epsilon_{I\mu\nu} \partial_\nu \Phi_I,$$

where $\epsilon_{I\mu\nu}$ is the Levi-Civita tensor $\epsilon_{0\cdots D - 1} = 1$ and $\gamma^{mn}$ is the inverse metric of $\gamma_{mn}$. One can obtain the following evolution equations for the Maxwell field potentials $\Phi_I$ and $\Psi$ from equations (4) and (5):

$$\Box \Phi_I = f^{JK} \nabla_J f_{IJ} \nabla_m \Phi_K - f^{-1} \nabla^m \nabla_\mu \omega_{I\mu} e^{2a\phi} + 2a \nabla^m \phi \nabla_m \Phi_I,$$

and

$$\Box \Psi = f^{-1} \nabla^m f \nabla_m \Psi + f^{IJ} \nabla^m \Phi_I \omega_{J\mu} e^{-2a\phi} - 2a \nabla^m \phi \nabla_m \Psi,$$

where $\nabla$ and $\Box = \nabla^m \nabla_m$ are the covariant differential operator and the d’Alembertian of $\gamma_{mn}$, respectively.

The equations for the dilaton field takes the form

$$\Box \phi = -\frac{a}{2} (e^{-2a\phi} f^{IJ} \nabla^m \Phi_I \nabla_m \Phi_J - e^{2a\phi} f^{-1} \nabla^m \Psi \nabla_m \Psi).$$

Now, we will write down the Einstein equations. From the mixed $(I, m)$-components of the Einstein equations (2) we have

$$\partial_\mu \omega_{I\nu} - \partial_\nu \omega_{I\mu} = 2(\partial_\nu \Phi_I \partial_\mu \Psi - \partial_\mu \Phi_I \partial_\nu \Psi).$$

From this, we can define the twist potential $Q_I$ such that

$$dQ_I + H_I = \omega_I + \Phi_I d\Psi - \Psi d\Phi_I,$$

where $H_I$ is a harmonic one-form for some given Riemannian metric on $\Sigma$ which is compact [CJ, CBM96]. For simplicity, we will suppose

$$H_I \equiv 0.$$

Evolution equations for $Q_I$ can be found by taking a three-covariant divergence of equation (14) taking account definition of $\omega_{I\mu}$ (9)

$$\Box Q_I = f^{-1} (\nabla^m f + \Psi \nabla^m \Psi)(\nabla_m Q_I - \Psi \nabla_m \Phi_I - \Phi_I \nabla_m \Psi) + f^{JK} (\nabla^m f_{IJ} + \Phi_I \nabla^m \Phi_J)(\nabla_m Q_K + \Psi \nabla_m \Phi_K - \Phi_K \nabla_m \Psi) + f^{-1} \Phi_I \nabla^m f \nabla_m \Psi - f^{JK} \Psi \nabla^m f_{IJ} \nabla_m \Phi_K.$$(16)
Next, evolution equations for the scalar multiplet $f_{IJ}$ follow from $(I,J)$-components of the Einstein equations (2):
\[
\Box f_{IJ} = f^{KL} \nabla^m f_{IK} \nabla_m f_{JL} - f^{-1}(\nabla^m Q_I + \Psi \nabla^m \Phi_I - \Phi_I \nabla^m \Psi)(\nabla_m Q_J + \Psi \nabla_m \Phi_J - \Phi_J \nabla_m \Psi) - 2e^{-2a\phi} \nabla^m \Phi_I \nabla_m \Phi_J + \frac{2}{D-2} f_{IJ} (e^{-2a\phi} f^{KL} \nabla^m \Phi_K \nabla_m \Phi_L - e^{2a\phi} f^{-1}\nabla^m \Psi \nabla_m \Psi). \tag{17}
\]

The effective Einstein equations on the three-spacetime whose metric is $\gamma$ follow from $(m,n)$ and $(I,J)$-components of the Einstein equations (2):
\[
\gamma R_{mn} = \frac{1}{4} (f^{-2} \nabla_m f \nabla_n f + f^{IJ} f^{KL} \nabla_m f_{IK} \nabla_n f_{JL}) - e^{-2a\phi} f^{IJ} \nabla_m \Phi_I \nabla_n \Phi_J + e^{2a\phi} f^{-1}\nabla^m \Psi \nabla_n \Psi + \frac{1}{2} f^{-1} f^{IJ} (\nabla_m Q_I + \Psi \nabla_m \Phi_I - \Phi_I \nabla_m \Psi)(\nabla_n Q_J + \Psi \nabla_n \Phi_J - \Phi_J \nabla_n \Psi) + 2 \nabla_m \phi \nabla_n \phi, \tag{18}
\]
where $\gamma R_{mn}$ is the Ricci tensor for $\gamma_{mn}$.

Note that the Maxwell equations (10) and (11) can be rewritten by using $Q_I$ as follows:
\[
\Box \Phi_I = f^{JK} \nabla^m f_{IJ} \nabla_m \Phi_K - f^{-1} \nabla^m \Psi(\nabla_m Q_I + \Psi \nabla_m \Phi_I - \Phi_I \nabla_m \Psi) e^{2a\phi} + 2a \nabla^m \phi \nabla_m \Phi_I, \tag{19}
\]
and
\[
\Box \Psi = f^{-1} \nabla^m f \nabla_m \Psi + f^{IJ} \nabla^m \Phi_I (\nabla_m Q_J + \Psi \nabla_m \Phi_J - \Phi_J \nabla_m \Psi) e^{-2a\phi} - 2a \nabla^m \phi \nabla_m \Psi. \tag{20}
\]
When $f_{IJ}$, $\gamma_{mn}$, $Q_I$, $\Phi_I$, $\Psi$ and $\phi$ are known on $\Sigma \times R$, we can get two-forms $W^I$ on $\Sigma \times R$, where
\[
W^I_{ij} = \partial_i W^I_j - \partial_j W^I_i = -f^{-1} f^{IJ} \sqrt{-\det \gamma} \epsilon_{ijm} \gamma^{mn} (\partial_m Q_J + \Psi \partial_m \Phi_J - \Phi_J \partial_m \Psi). \tag{21}
\]
We can deduce from $W^I$ one-forms $\Theta^I$ on $\mathcal{M}_D$ if and only if the following two conditions hold [CJ, CBM96]. One is a local condition which is the system of evolution equations. Another is a global condition. Since each $U(1)$-symmetric one-form $\Theta^I$ is independent, in the case $\Sigma$ compact, $G_{D-3} = T^{D-3}$, the global condition reads
\[
n_I = \frac{1}{2\pi} \int_\Sigma d\Theta^I = \frac{1}{2\pi} \int_\Sigma W^I, \quad (n_I \in \mathbb{Z}). \tag{22}
\]
In summary, the following action describing a wave map coupled to three-dimensional gravity is obtained as an effective action:
\[
S_3 = \int d^3x \sqrt{-\det \gamma} \left[ -\gamma R + \frac{1}{4} f^{-2} \nabla^m f \nabla_m f + \frac{1}{4} f^{IJ} f^{KL} \nabla^m f_{IK} \nabla_m f_{JL} + e^{-2a\phi} f^{IJ} \nabla^m \Phi_I \nabla_m \Phi_J + e^{2a\phi} f^{-1}\nabla^m \Psi \nabla_m \Psi + 2 \nabla^m \phi \nabla_m \phi + \frac{1}{2} f^{-1} f^{IJ} (\nabla^m Q_I + \Psi \nabla^m \Phi_I - \Phi_I \nabla^m \Psi)(\nabla_m Q_J + \Psi \nabla_m \Phi_J - \Phi_J \nabla_m \Psi) \right], \tag{23}
\]
where $\gamma R$ is the Ricci scalar for $\gamma_{mn}$. It is easy to show that the evolution equations, (12), (16), (17), (19), (20), and the three-dimensional Einstein equations (18) are obtain from this action (23). The only wave map consisting of scalar fields has dynamical degrees of freedom, but three-dimensional gravity does not have ones.

3 Global existence theorem for $T^{D-2}$-symmetric spacetimes in areal time coordinate

We will consider $G_{D-2} = U(1) \times \cdots \times U(1) = T^{D-2}$-invariant cosmological spacetimes. That is, we assume the existence of another spacelike Killing vector field $\xi_2 = \partial_2$ which commutes with the other Killing vectors $[\xi_2, \xi_I] = 0$. The Maxwell and the dilaton fields are also assumed to be independent of the
coordinate $x^2$. Thus, $\mathcal{M}_{D-1}$ can be parametrized by $x^2$ and $x^1 = \theta \in \mathcal{M}_{D-1}/G_{D-2} \approx [0, 2\pi]_{\mod 2\pi} \approx S^1$, where $I = 2, \ldots, D - 1$. The Frobenius integrability condition is [DFC]

$$\xi^\mu_{\nu} \cdots \xi_{D-1}^{\mu_{D-1}} \partial^{\nu} \xi_T] = 0. \quad (24)$$

Spacetimes satisfying the above condition admit a foliation by two-dimensional integrable surfaces orthogonal to the Killing fields $\xi_T$. From equation (9) one can obtain that the condition (24) for $I = 1$ is

$$\omega_I = 0. \quad (25)$$

The equations (25) are satisfied if they hold somewhere at one point in the spacetimes. Indeed, we have the following equation by (13):

$$\partial_\mu \omega_I = 2(\partial_2 \Phi_I \partial_\mu \Psi - \partial_\mu \Phi_I \partial_2 \Psi) = 0, \quad (26)$$

because of $\partial_2 \Phi_I = \partial_2 \Psi = 0$. Since it need not to distinguish $\xi_2$ from $\xi_I$, the Frobenius integrability condition (24) is satisfied for $I$ if equations (25) hold at least one point $^2$. Hereafter, we assume this hypersurface-orthogonality condition.

Under the above assumption, the line element of the spacetimes takes the $2 \times 2\cdot (D - 2) \times (D - 2)$ block-diagonal form. Thus, the three-dimensional Lorentzian metric can be written in the form

$$\gamma_{ij} = e^{2\lambda(-dt^2 + d\theta^2)} + \rho^2 d\psi^2, \quad W_0^I = W_1^I = 0, \quad (27)$$

where $t = x^0$, $\psi = x^2$, $\lambda = \lambda(t, \theta)$ and $\rho = \rho(t, \theta)$. Here, we have used the fact that two-dimensional spacetime (which is spanned by $t$ and $\theta$-coordinates) can be conformal flat. In this coordinate, we have a linear wave equation for $\rho$ from the Einstein equations (18) for three-spacetime,

$$(\partial_t^2 - \partial_\theta^2) \rho = 0. \quad (28)$$

By using equation (28) and the same argument with Gowdy [GR], we can take areal time coordinate $\rho = t$. Then, the spacetime metric is

$$g = f^{-1}[e^{2\lambda(-dt^2 + d\theta^2)} + t^2 d\psi^2] + f_{I,J}(dx^I + W^I d\psi)(dx^J + W^J d\psi), \quad (29)$$

where the metric functions depend only on $t$ and $\theta$. The same dependence is assumed for functions of matter fields. Note that a metric of $T^3$-Gowdy symmetric spacetimes would be induced from the metric (29) if $D = 4$ [GR].

In the areal time coordinate (29), we have constraint equations from (18) as follows:

$$2t^{-1} \partial_t \lambda = \frac{1}{4} f^{-2}[(\partial_t f)^2 + (\partial_\theta f)^2] + \frac{1}{4} f^{I,J} f^{MN}(\partial_t f_{IJ} \partial_t f_{MN} + \partial_\theta f_{IJ} \partial_\theta f_{MN})$$

$$+ e^{-2a \phi} f^{I,J}((\partial_t \Phi_I \partial_\theta \Phi_J + \partial_\theta \Phi_I \partial_t \Phi_J) + e^{2a \phi} f^{-1}[(\partial_t \Psi)^2 + (\partial_\theta \Psi)^2]$$

$$+ \frac{1}{2} f^{-1}(J^I [((\partial_t Q_I + \Psi \partial_t \Phi_I - \Phi_I \partial_t \Psi) (\partial_\theta Q_J + \Psi \partial_\theta \Phi_J - \Phi_J \partial_t \Psi)$$

$$+ (\partial_\theta Q_I + \Psi \partial_\theta \Phi_I - \Phi_I \partial_\theta \Psi) (\partial_\theta Q_J + \Psi \partial_\theta \Phi_J - \Phi_J \partial_\theta \Psi)]$$

$$+ 2[(\partial_t \phi)^2 + (\partial_\theta \phi)^2], \quad (30)$$

$$t^{-1} \partial_\theta \lambda = \frac{1}{4} f^{-2} \partial_t f \partial_\theta f + \frac{1}{4} f^{I,J} f^{MN}(\partial_t f_{IJ} \partial_\theta f_{MN}$$

$$+ e^{-2a \phi} f^{I,J} \partial_t \Phi_I \partial_\theta \Phi_J + e^{2a \phi} f^{-1} \partial_\theta \Psi)$$

$$+ \frac{1}{2} f^{-1}(J^I [((\partial_t Q_I + \Psi \partial_t \Phi_I - \Phi_I \partial_t \Psi) (\partial_\theta Q_J + \Psi \partial_\theta \Phi_J - \Phi_J \partial_\theta \Psi)$$

$$+ 2\partial_t \phi \partial_\theta \phi), \quad (31)$$

$^2$In the case of four-dimensional $U(1) \times U(1)$-symmetric spacetimes, it is known that the above assumption corresponds to vanishing twist constants in the case of $T^3$-spatial topology. In addition, if there is a symmetry axis in the spatial section, like $S^2 \times S^1$, the condition (25) holds at the axis, then the hypersurface-orthogonality is automatically satisfied [CP].
The integrability condition $\partial_\ell \partial_\theta \lambda = \partial_\theta \partial_\lambda$ of equations (30) and (31) is assured whenever the other evolution equations are satisfied. Note that we can obtain an evolution equation for $\lambda$ from equations for others.

$$
\begin{align*}
\partial_\ell^2 \lambda - \partial_\theta^2 \lambda &= \frac{1}{4} f^{-2} \left[ - (\partial_\ell f)^2 + (\partial_\theta f)^2 \right] + \frac{1}{4} f^{IJ} f^{MN} \left( - \partial_\ell f_{1M} \partial_\ell f_{JN} + \partial_\theta f_{1M} \partial_\theta f_{JN} \right) \\
&\quad + e^{-2aT} f^{IJ} \left( \Phi_I \Phi_J - \partial_\ell \Phi \partial_\ell \Phi - \Phi \partial_\theta \Phi - \Phi \partial_\theta \Phi \right) + e^{2aT} f^{-1} \left[ - (\partial_\ell \Psi)^2 + (\partial_\theta \Psi)^2 \right] \\
&\quad + \frac{1}{2} f^{-1} f^{IJ} \left[ - (\partial_\ell Q_I + \partial_\theta \Phi - \Phi \partial_\ell \Psi - \Phi \partial_\theta \Psi) \right] \\
&\quad + (\partial_\theta Q_I + \partial_\ell \Phi - \Phi \partial_\ell \Psi) \left( \partial_\theta Q_J + \partial_\ell \Phi - \Phi \partial_\theta \Psi \right) \\
&\quad + 2 \left[ - (\partial_\ell \phi)^2 + (\partial_\theta \phi)^2 \right]. 
\end{align*}
$$

(32)

Thanks to the areal time coordinate, the metric function $\lambda$ is decoupled with other fields. Therefore, it is enough to solve the evolution equations at first. After that, we must demand compatibility conditions for $\lambda$. That is, equations (30) and (31) are ones to determine the metric function $\lambda$. Under the coordinate (29), we will call a system of equations (12), (16), (17), (19), (20), (30), (31) $T^{D-2}$-symmetric EMD system.

Now, we have the following conclusion by direct calculation:

**Lemma 1** Let $M = \mathbb{R} \times T^2$ and $N = \mathbb{R}^{2(D-2)(D+1)}$ be manifolds with Lorentzian metric $\eta$ and Riemannian metric $h$, respectively. Then, a wave map $U : M \rightarrow N$ is equivalent to the evolution equations (12), (16), (17), (19), (20), of the $T^{D-2}$-symmetric EMD system. Here, the action for the wave map is

$$
S_{WM} = \int dt d\theta d\psi L_{WM} = \int dt d\theta d\psi \sqrt{-\det \eta^{\alpha\beta} h_{\alpha\beta} U^A \partial_\alpha U^B},
$$

(33)

and the metrics are

$$
\eta := -dt^2 + d\theta^2 + t^2 d\psi^2, \quad 0 \leq \theta, \psi \leq 2\pi,
$$

(34)

and

$$
\begin{align*}
h &= \frac{1}{4} f^{IJ} f^{KL} dQ_I dQ_J + e^{-2aT} f^{IJ} d\Phi_I d\Phi_J + e^{2aT} f^{-1} d\Psi^2 \\
&\quad + \frac{1}{2} f^{IJ} \left( \partial_\ell Q_I + \partial_\theta \Phi - \Phi \partial_\ell \Psi - \Phi \partial_\theta \Psi \right) \left( \partial_\ell Q_J + \partial_\theta \Phi - \Phi \partial_\ell \Psi - \Phi \partial_\theta \Psi \right) + 2 d\phi^2. 
\end{align*}
$$

(35)

Note that $U$ is independent of $\psi$. \hfill \Box

The integrals (22) are independent of time $t$. This fact follows from Noether’s theorem [BCM, SS]. Let $Z$ be a Killing vector for the metric $h$ given by (35). It is well known that the following quantity is independent of the choice of compact Cauchy hypersurfaces,

$$
E(Z, S) = \int_S \eta^{\alpha\beta} h_{\alpha\beta} \frac{\partial U^A}{\partial x^\alpha} Z^B dS_\beta,
$$

(36)

where $\alpha, \beta = t, \theta, \psi, U^A = (P_I, Q_I, \Phi, \Psi \phi)^T$ and $dS_\beta = \partial_\alpha \nabla (dt \wedge d\theta \wedge d\psi)$, and $\nabla$ denotes contraction. It is easy to see that $\partial_{Q_I}$ are Killing vectors for the metric $h$. Taking $Z = \partial_{Q_I}$ and $S = \{ t = \text{constant} \} = \Sigma$ one obtains the integrals (22). Thus, they are conservation quantities when the wave map system holds.

Although Lemma 1 is quite general and useful, geometry of the target space $(N, h)$ is very complicated since scalar multiplet $f_{IJ}$ does not be fixed. Therefore, to analyze the system furthermore, we assume the following,

$$
f_{IJ} = e^{2P_I} \delta_{IJ},
$$

(37)

and $P = \sum_I P_I$. This assumption does not restrict to diagonal (i.e. polarized) spacetimes. Indeed, our $T^{D-2}$-symmetric spacetimes with the assumption include four-dimensional unpolarized Gowdy symmetric
ones as a special case. Under the assumption (37), the metric of the target space can be written by

\[ h = dP^2 + \sum_{l=3}^{D-1} \frac{e^{-2P_l} d\Phi_l^2}{2} + \frac{1}{2} e^{-2P} \sum_{l=3}^{D-1} e^{-2P_l} (dQ_l + \Phi d\Phi_l - \Phi_l d\Phi)^2 + 2d\phi^2. \]  

(38)

For this target space, we can show the following global existence theorem:

**Theorem 1** Let \((\mathcal{M}_D, g_{\mu\nu}, A_{\mu}, \phi)\) be the maximal Cauchy development of smooth \(T^{D-2}\)-symmetric Cauchy data on \(\mathcal{M}_{D-1} \approx T^{D-1}\) for the \(T^{D-2}\)-symmetric EMD system. Then, under the assumption (37), \(\mathcal{M}_D\) can be covered by the areal time coordinate with \(t \in (0, \infty)\).

It is known the local existence result for the wave map system (e.g. Theorem 7.1 of \([SS]\)). Therefore, it is enough to show boundedness for the sup norm of the zeroth, the first and the second derivatives of the functions on compact subinterval of \((0, \infty)\) for time coordinate \(t\).

Let us define the energy-momentum tensor \(T_{\alpha\beta}\) associated with the Lagrangian density (33), which has the form

\[ T_{\alpha\beta} := h_{AB}(\partial_\alpha U^A \partial_\beta U^B - \frac{1}{2} \eta_{\alpha\beta} \partial_\alpha U^A \partial_\beta U^B). \]  

(39)

Components of \(T_{\alpha\beta}\) are as follows, with \(\langle , \rangle\) and \(\| \cdot \|\) denoting the inner product and the norm with respect to \(h\),

\[ T_{\alpha\beta} = \begin{pmatrix}
T_{tt} & T_{t\theta} & T_{t\psi} \\
T_{\theta t} & T_{\theta\theta} & T_{\theta\psi} \\
T_{\psi t} & T_{\psi\theta} & T_{\psi\psi}
\end{pmatrix} = \frac{1}{2} \begin{pmatrix}
\|\partial_t U\|^2 + \|\partial_\theta U\|^2 & 2(\partial_t U, \partial_\theta U) & 0 \\
2(\partial_\theta U, \partial_t U) & \|\partial_\theta U\|^2 + \|\partial_\psi U\|^2 & 0 \\
0 & 0 & t^2(\|\partial_t U\|^2 - \|\partial_\theta U\|^2)
\end{pmatrix} \]

(40)

Note that equations for \(\lambda\) can be simplify by these quantities as follows:

\[ \partial_\lambda \lambda = tE, \]
\[ \partial_\theta \lambda = tF, \]
\[ \partial_\psi \lambda = -t^2G. \]

(41), (42), (43)

By using light cone estimate \([MV]\) and Christodoulou-Tahvildar-Zadeh’s identity \([CTZ]\), we have the following lemma:

**Lemma 2 (Lemma 2 of [NM03])** There is a positive constant \(C\) such that

\[ E \leq C \left[ 1 + \frac{1}{t^2} \right], \quad t \in (0, \infty), \]

(44)

where \(C\) depends only on the initial data at \(t = t_0\). \(\square\)

**Proof of Theorem 1:** From lemma 2, we have the desired bounds on \( |\partial_t P|, |\partial_\theta P|, |\partial_\psi P|, |\partial_t P_t|, |\partial_\theta P_t|, |\partial_\psi P_t|, |\partial_\psi (\partial_\theta + P_t)|, |\partial_\psi (\partial_t + P_t)|, |\partial_\phi |, |\partial_\theta \phi |, |\partial_\psi \phi |, |\partial_\phi \phi |, |\partial_\theta \phi \phi |, |\partial_\psi \phi \phi |\) for all \( t \in (0, \infty) \). Once we have bounds on the first derivatives of \(P, P_t\) and \(\phi\), it follows that \(P, P_t\) and \(\phi\) are bound for all \( t \in (0, \infty) \). Then, we have bounds on \(\partial_t \Phi_1, \partial_\theta \Phi_1, \partial_\psi \Phi_1, \partial_\psi Q_1, \Phi_1 \partial_\theta \Phi_1 + \Psi \partial_\theta \Phi_1 - \Phi_1 \partial_\theta \Psi\). Consequently, \(\Phi_1, \Psi, \partial_\psi Q_1\) and \(\partial_\theta Q_1\) are bounded. Finally, we have boundedness on \(Q_1\).

Next, we must show bounds on the second and higher derivatives of the functions. There is a well-known general fact that, in order to ensure the continuation of a solution of a system of semi-linear wave
equations, it is enough to bound the first derivative pointwise. Then, we have boundedness of the higher
derivatives.

By the constraint equations (41) and (42), boundedness and compatibility with the periodicity in \( \theta \)
for the function \( \lambda \) is also shown. The arguments for that are the same with one of the proof of Theorem
1 of [NM03]. Thus, we have completed the proof of Theorem 1.

4 Global existence theorem in constant mean curvature (CMC)
time coordinate

To show a global existence theorem in CMC time coordinate for \( T^{D-2} \)-symmetric spacetimes, Henkel’s ob-
ervation is applicable [HO]. He has considered prescribed mean curvature foliations in locally \( U(1) \times U(1) \)-symmetric four-dimensional spacetimes with matter fields. The system of our \( D \)-dimensional spacetimes is similar with one treated in that paper\(^3\). One difference between Henkel’s and ours is target spaces of
the wave maps. Fortunately, arguments in the proofs of Propositions 5.4-5.6 of [HO] do not depend on
properties of the target spaces. In addition, we need not estimate functions of matter fields separately
since the field equations of the matter fields are included in the wave map system in our case. Thus, from
negativity of mean curvature of areal time slices,

\[
K = -e^{P-\lambda} \left[ \partial_t \lambda - \partial_t P + \frac{1}{t} \right] \leq -\frac{3e^{P-\lambda}}{4t} < 0, \quad t \in (0, \infty),
\]

(45)

(where equation (41) has used) the spacetimes has crushing singularity into the past and thus a neighbor-
hood near the singularity can be foliated by compact CMC hypersurfaces [GC]. Once we have one
compact CMC hypersurface with negative mean curvature, it is shown that the CMC foliation covers the
entire future of the initial CMC hypersurface (see [ARR]). Thus, the following theorem is obtained:

**Theorem 2** Let \((M_D, g_{\mu \nu}, A_\mu, \phi)\) be the maximal Cauchy development of smooth \( T^{D-2} \)-symmetric Cauchy
data on \( M_{D-1} \approx T^{D-1} \) for the \( T^{D-2} \)-symmetric EMD system. Then, under the assumption (37), \( M_D \)
can be covered by hypersurfaces of the constant mean curvature in the range \((-\infty, 0)\).

5 Existence of asymptotically velocity-terms dominated (AVTD)
solutions

5.1 Analytic case

5.1.1 Generalities

As a method to construct AVTD singular solutions, the *Fuchsian algorithm* has been developed [KR]. To
answer the question rigorously whether the AVTD behavior exists or not for vacuum Einstein gravity in
arbitrary spacetime dimension, the algorithm will be used.

Now, we briefly review the Fuchsian algorithm. Let us consider a hyperbolic PDE system,

\[
F[u(t, x^\alpha)] = 0.
\]

(46)

Generically, \( u \) can have any number of components. Here, we will assume that the PDE is singular
with respect to the argument \( t \). The Fuchsian algorithm consists of three steps: At first, identify the
leading (singular) terms \( u_0(t, x) \) which are parts of the desired expansion for \( u \). This means that the most
singular terms cancel each other when \( u_0(t, x) \) is substituted in equation (46). One can get the solution
\( u_0 \) from a system of velocity-terms-dominated (VTD) equations which are obtained by neglecting spatial
derivative terms from full equations (46). Second, introduce a renormalized unknown function \( v(t, x) \),
which is given by

\[
u = u_0 + t^m \tilde{u}.
\]

(47)

\(^3\)Rather, our system is simpler than Henkel’s because there is no shift vector in ours.
If \( u_0 \sim t^k \), we should set \( m = k + \varepsilon \), where \( \varepsilon > 0 \). Thus, \( \tilde{u} \) is a regular part of the desired expansion for \( u \). Finally, obtain a Fuchsian system for \( \tilde{u} \) by substituting equation (47) in equation (46). That is,

\[
(D + N(x))\tilde{u} = t^n V(t, x, \tilde{u}, \partial_x \tilde{u}),
\]

where \( D := t\partial_t \) and \( N \) is a matrix which is independent of \( t \) and \( \alpha > 0 \). Note that one can always take \( \alpha = 1 \) by introducing \( t^n \) as a new time variable. \( V \) can be assumed to be analytic in all of arguments except \( t \) and continuous in \( t \) since the following existence theorem (Theorem 3) is a singular version of the Cauchy-Kowalewskaya theorem essentially. Note that equation (48) is a singular PDE system for the regular function \( v \).

Once we have the Fuchsian system, we can show the existence of a unique solution for prescribed singular part \( u_0 \) by the following theorem.

**Theorem 3 (Theorem 3 of [KR])** Let us consider a system (48), where \( N \) is an analytic matrix near \( x = 0 \), such that \( \|\sigma^N\| \leq C \) for \( 0 < \alpha < 1 \) (boundedness condition) and \( V \) is analytic in space \( x \) and continuous in time \( t \). Then the Fuchsian system (48) has a unique solution which is defined near \( x = 0 \) and \( t = 0 \), and which is analytic in space \( x \) and continuous in time \( t \), and tend to zero as \( t \to 0 \). \( \square \)

Note that the boundedness condition holds if every eigenvalue of \( A \) is non-negative. Theorem 3 implies that renormalized unknown functions must vanish as \( t \to 0 \) if the conditions are satisfied. Therefore, the only singular terms which are solutions to VTD equations remain and they are solutions to full field equations at \( t = 0 \). Thus, we obtain AVTD singular solutions.

### 5.1.2 Application to vacuum \( T^{D-2} \)-symmetric spacetimes

As mentioned in Section 1, it is interesting for us in the vacuum case. Let us take \( \Phi_I := \Psi = \phi = a = 0 \). Then, we obtain a metric of the target space of the wave map from (38),

\[
h = dP^2 + \sum_{I=3}^{D-1} dP^2_I + \frac{1}{2} e^{-2P} \sum_{I=3}^{D-1} e^{-2P_I} dQ_I^2. \tag{49}
\]

By Lemma 1 (or equations (17) and (16)) we have a system of evolution equations for vacuum Einstein gravity as follows:

\[
\mathcal{D}^2 P_I - t^2 \partial_\theta^2 P_I = -\frac{1}{2} e^{-2(P+P_I)}(\mathcal{D}Q_I)^2 - (t\partial \theta Q_I)^2, \tag{50}
\]

\[
\mathcal{D}^2 Q_I - t^2 \partial_\theta^2 Q_I = 2[D(P + P_I)\mathcal{D}Q_I - t^2(\partial \theta P + \partial_\theta P_I)\partial \theta Q_I]. \tag{51}
\]

Neglecting spatial derivative terms from equations (50)-(51), one can obtain VTD equations as follows:

\[
\mathcal{D}^2 P_I = -\frac{1}{2} e^{-2(P+P_I)}(\mathcal{D}Q_I)^2, \tag{52}
\]

\[
\mathcal{D}^2 Q_I = 2[D(P + P_I)\mathcal{D}Q_I]. \tag{53}
\]

From these equations (52)-(53) we can find VTD solutions as follows:

\[
P_I^{\text{VTD}}(t, \theta) = p_{10}(\theta) \ln t + p_{11}(\theta), \tag{54}
\]

\[
Q_I^{\text{VTD}}(t, \theta) = q_{10}(\theta) + t^{2(p_0+p_{10})} q_{11}(\theta), \tag{55}
\]

where \( p_0 := \sum_I p_{10} \). Hereafter we put \( k_I := p_0 + p_{10} \). Thus, the following formal solutions which have the leading terms \( P_I^{\text{VTD}} \) and \( Q_I^{\text{VTD}} \) are obtained:

\[
P_I(t, \theta) = P_I^{\text{VTD}} + t^{\epsilon_I} \pi_I(t, \theta), \tag{56}
\]

\[
Q_I(t, \theta) = Q_I^{\text{VTD}} + t^{2k_I} \kappa_I(t, \theta), \tag{57}
\]

where \( \epsilon_I > 0 \) and \( k_I > 0 \).

\[^4\text{In this case, the dilaton and the Maxwell equations (12), (19), (20) are automatically satisfied.}\]
Let us be \( \bar{\pi}_I := (\pi_{0I}, \pi_{1I}, \pi_{2I}) := (\pi_I, D\pi_I, t\partial_0\pi_I) \) and \( \bar{\kappa} := (\kappa_{0I}, \kappa_{1I}, \kappa_{2I}) := (\kappa_I, D\kappa_I, t\partial_0\kappa_I) \). From these, we define \( v := (\bar{\pi}_I, \bar{\kappa}_I)^T \). We have a Fuchsian system for \( v \) by inserting solutions \((56)\) and \((57)\) into the system \((50)\) and \((51)\):

\[
(D + N)v = t^\delta V(t, \theta, v, \partial_0v),
\]

where \( \delta = \min\{2k_I - \epsilon_I, 2(1 - k_I) - \epsilon_I, \epsilon_I\} \) for any \( I \), \( V \) is a vector-valued regular function and \( N \) is

\[
N = \begin{bmatrix}
N_{\epsilon_3} & \cdots & \cdots & 0 \\
\cdots & \cdots & \cdots & \cdots \\
0 & \cdots & \cdots & N_{\kappa_{D-1}} \\
\end{bmatrix},
\]

where

\[
N_{\epsilon_I} := \begin{bmatrix} 0 & -1 & 0 \\ \epsilon_I^2 & 2\epsilon_I & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad \text{and} \quad N_{\kappa_I} := \begin{bmatrix} 0 & -1 & 0 \\ 0 & 2k_I & 0 \\ 0 & 0 & 0 \end{bmatrix},
\]

which are independent of \( t \). It is easy to see that every eigenvalue of \( N \) is non-negative and regularity of the right-hand-side of the system \((58)\) holds if and only if \( 0 < \epsilon_I < \min\{2k_I, 2(1 - k_I)\} \), i.e. \( 0 < k_I < 1 \). Thus, we have the following theorem from Theorem 3.

**Theorem 4** Let \( p_I A(\theta), q_I A(\theta) \), where A = 0, 1, be real analytic functions of \( \theta \) in a neighborhood of \( \theta = \theta_0 \) and \( 0 < k_I < 1 \) for all \( \theta \). Then, for the vacuum Einstein equations \((50)\) and \((51)\) in arbitrary dimensions \((D \geq 4)\), there exists a unique solution with the form \((56)\) and \((57)\) in a neighborhood of \( \theta = \theta_0 \), where \( \pi_I, \kappa_I \) tend to zero as \( t \to 0 \).

Theorem 4 implies that VTD solutions \( P_I^{VTD}(t, \theta) \) and \( Q_I^{VTD}(t, \theta) \) are solutions to full Einstein equations \((50)\) and \((51)\) near the initial singularity. The VTD solutions depend on the maximal number (i.e. \( 4 \times (D - 3) \)) of arbitrary functions \( p_I A(\theta) \) and \( q_I A(\theta) \). Thus, it has been shown that \( T^{D-2} \)-symmetric vacuum spacetimes on \( T^{D-1} \times \mathbb{R} \) have AVTD behavior in general.

### 5.2 Smooth case

#### 5.2.1 Generalities

The argument in this subsection has been developed by Rendall [RA] (which was generalized in [SF]). We will review it, which is a smooth version of the Fuchsian algorithm.

We want to extend to the \( C^\infty \) category of the existence of AVTD singular solutions. To do this, we introduce notions of regularity and formal solutions of equation \((48)\).

**Definition 1** A function \( f(t, x) \) from an open subset \( \Omega \subset [0, \infty) \times \mathbb{R}^n \) to \( \mathbb{R}^m \) is called regular if it is \( C^\infty \) for all \( t > 0 \) and if its partial derivatives of any order with respect to \( x \in \mathbb{R}^n \) extend continuously to \( t = 0 \) (within \( \Omega \)).

**Definition 2** A finite sequence \((v_1, \ldots, v_p)\) of functions defined on an open subset \( \Omega \subset [0, \infty) \times \mathbb{R}^n \) is called a formal solution of order \( p \) of the differential equation \((48)\) on \( \Omega \) if

1. each \( v_i \) is regular and
2. \((D + N(x))v_i - tv(t, x, v_i, \partial_x v_i) = O(t^i) \) for all \( i \) as \( t \to 0 \) in \( \Omega \), where \( O \)-symbol is taken in the sense of uniform convergence on compact subsets.

If functions \( N \) and \( V \) in \((48)\) are analytic ones, existence of analytic solutions can be shown [KR]. Contrary, if \( N \) and \( V \) are merely smooth, the following existence theorem for formal solutions of any order is obtained:
Theorem 5 (Section 4 of [RA] and Theorem 5.1 of [SF] (see also Theorem 2.3 of [KS]))

Let \( z_m(t,x) \) be a sequence of regular solutions on \([0,t_1) \times U \subset [0,\infty) \times \mathbb{R}^n \), with \( z_m(0,x) = 0 \), to a sequence of RSH equations

\[
\{ A^0_m(t,x)D + N_m(t,x) + tA_m(t,x,z_m)\partial_j \} z_m = tV_m(t,x,z_m).
\]
Suppose that $N_m$ is positive definite for each $m$ and that the coefficients converge uniformly to $A^0_{\infty}$, $N_{\infty}$, $A_{\infty}$ and $V_{\infty}$ on compact subsets as $m \to \infty$, with the same properties as $A_m$, $N_m$, $A_m^0$ and $V_m$, and that the corresponding spatial derivatives converge uniformly as well. Then $z_m$ converges to a regular solution $z_{\infty}$ of the corresponding system with coefficients $A^0_{\infty}$, $N_{\infty}$, $A_{\infty}$ and $V_{\infty}$ on $[0,t_0) \times U$ for some $t_0$, and $z_{\infty}(0,x) = 0$. 

Here, we have fixed a value of $i$ large enough and omitted the index $i$.

Finally, we must verify that the obtained smooth solution of (61) is also a solution to (58). When the above arguments be done, the proof of the existence of smooth VTD solutions completes.

### 5.2.2 Low velocity case

Now, we will rewrite the Fuchsian system (58) to a RSH system as follows:

\[
(D + N + t A^0 \partial_\theta) v = t^\zeta \mathcal{V}(t, \theta, v, \partial_\theta v),
\]

where $\zeta = \min\{2k_I - \epsilon_j, 2(1 - k_I) - \epsilon_j, 1 - 2k_I + \epsilon_j, \epsilon_j\}$ for any $I$ and $J$, $\mathcal{V}$ is a vector-valued regular functions and

\[
N = \begin{bmatrix}
N_{\epsilon_1} & \cdots & N_{\epsilon_{D-1}} \\
& \ddots & \\
& & N_{k_{D-1}}
\end{bmatrix},
\]

where

\[
N_{\epsilon_I} := \begin{bmatrix} 0 & -1 & 0 \\
\epsilon_I^2 & 2\epsilon_I & 0 \\
0 & 0 & -1 \end{bmatrix} \quad \text{and} \quad N_{k_I} := \begin{bmatrix} 0 & -1 & 0 \\
0 & 2k_I & 0 \\
0 & 0 & -1 \end{bmatrix},
\]

and

\[
A^0 = \begin{bmatrix} A_{\text{Her}} & \cdots & A_{\text{Her}} \\
& \ddots & \\
& & A_{\text{Her}}
\end{bmatrix}, \quad \text{where} \quad A_{\text{Her}} := \begin{bmatrix} 0 & 0 & 0 \\
0 & 0 & -1 \\
0 & -1 & 0 \end{bmatrix},
\]

which are independent of $t$. In our case, $A^0$ becomes the identity. The regularity of the right-hand-side of (64) is satisfied if $0 < k_I < 3/4$ for any $I$.

We must verify that solutions to the Fuchsian system (58) are also solutions to the RSH system (64). The system (64) is obtained by replacing $t \partial_\theta \pi_{0I}$ and $t \partial_\theta \kappa_{0I}$ with $\pi_{2I}$ and $\kappa_{2I}$, respectively. For analytic solutions, the system (58) implies $D(t \partial_\theta \pi_{0I} - \pi_{2I}) = 0$ and $D(t \partial_\theta \kappa_{0I} - \kappa_{2I}) = 0$. Since $t \partial_\theta \pi_{0I} - \pi_{2I} = 0$ and $t \partial_\theta \kappa_{0I} - \kappa_{2I} = 0$ at $t = 0$, we can conclude that these equations are satisfied in all time. Thus, an analytic solution of (58) is an analytic solution of (64). Repeating this argument for formal solutions of order $i$ to the Fuchsian system (58), we have the same conclusion for formal solutions.

Next, we want to apply Theorem 5 to our system (64). As we can see from (62) and (66), it is enough to take $i \geq 3$, where $i$ is the order for the formal solution. Then, we have a smooth solution to the RSH system (64).

Finally, we have to show that the obtained solution to (64) is also a solution to the Fuchsian system (58). From (64) and the fact that $\bar{\pi}$ and $\bar{\kappa}$ are vanish at $t = 0$, we have $\pi_{2I} = t \partial_\theta \pi_{0I} = c_I^\theta(\theta) t$ and $\kappa_{2I} = t \partial_\theta \kappa_{0I} = c_I^\gamma(\theta) t$ for some functions $c_I^\theta(\theta)$ and $c_I^\gamma(\theta)$. Suppose analytic functions converging to $\bar{\pi}$ and $\bar{\kappa}$ be $\pi_m$ and $\kappa_m$. Then, we have

\[
\sup_{\theta} | c_I^\theta(\theta) t | \leq \sup_{\theta} | (\pi_{2I} - t \partial_\theta \pi_{0I}) - (\pi_{2I_m} - t \partial_\theta \pi_{0I_m}) | \leq \sup_{\theta} | \pi_{2I} - \pi_{2I_m} | + \sup_{\theta} | \partial_\theta \pi_{0I} - \partial_\theta \pi_{0I_m} | \to 0,
\]

(68)
for any \( t \) as \( m \to \infty \). Here, equations \( \pi_{2lm} - t \partial_\theta \pi_{0lm} = 0 \) for any \( m \) has been used. Thus, \( \pi_{2l} - t \partial_\theta \pi_{0l} = 0 \) was shown for all time. \( \kappa_{2l} - t \partial_\theta \kappa_{0l} = 0 \) can be also proved similarly. Thus, it was shown that the smooth solution of the RSH system (64) is also a smooth solution to the original Fuchsian system (58). To sum up,

**Theorem 6** Suppose that \( p_{IA} \) and \( q_{IA} \) are smooth functions of \( \theta \) and \( 0 < k_l < 3/4 \) for all \( \theta \). Then, for each spatial point \( \theta = \theta_0 \), there exists a solution of the Einstein equations (50) and (51) in a neighborhood of \( \theta = \theta_0 \) of the form (56) and (57) where \( 2k_I - 1 < \epsilon_I < \min\{2k_I - 1, 2 - 2k_I\} \) for any \( I \) and \( J \), and \( \pi_I \) and \( \kappa_I \) are regular and tend to 0 as \( t \to 0 \). Given the form of the expansion and a choice of \( \epsilon_I \), the solution is unique. □

### 5.2.3 Intermediate velocity case

We want to complement the whole range \( 0 < k_I < 1 \) arising in Theorem 4. Now, the following candidates for solutions to the vacuum Einstein equations will be considered:

\[
P_I(t, \theta) = P_I^{\text{YTD}}(t, \theta) + \sum_{\epsilon_I} \sum_{J} \alpha_{IJ} \frac{\partial^2 \theta_{10}}{2 - 2k_I} \exp \left[ -2(p_{IJ} + \sum_{J=3}^{D-1} p_{JJ}) \right],
\]

(69)

\[
Q_I(t, \theta) = Q_I^{\text{YTD}}(t, \theta) + \sum_{\epsilon_I} \sum_{J} \pi_{IJ} \kappa_I(t, \theta),
\]

(70)

where \( \epsilon_I > 0 \) and \( k_I > 0 \) and \( \alpha_{IJ} \) are chosen as follows:

\[
\alpha_{IJ} = \frac{1}{2} \left( \frac{\partial^2 \theta_{10}}{2 - 2k_I} \right)^2 \exp \left[ -2(p_{IJ} + \sum_{J=3}^{D-1} p_{JJ}) \right].
\]

(71)

Therefore, the number of arbitrary functions is \( 4 \times (D - 3) \) still. Solutions (70) are the same with (57). Substituting (69) and (70) into the vacuum Einstein equations (50) and (51), the following RSH system is obtained:

\[
(D + \tilde{N} + t\mathcal{A}^\theta \partial_\theta) v = t \tilde{\mathcal{V}}(t, \theta, v, \partial_\theta v),
\]

(72)

where \( \tilde{\mathcal{V}} = \min(2 - 2k_I - \epsilon_J, 3 - 2(k_I + k_J) + \epsilon_J, 2k_I - 1 - \epsilon_J) \) for any \( I \) and \( J \), \( \tilde{\mathcal{V}} \) is a vector-valued regular functions and

\[
\tilde{N} = \begin{bmatrix}
\tilde{N}_e_3 \\
\vdots \\
\tilde{N}_{E-1} \\
\tilde{N}_{k_3} \\
\vdots \\
\tilde{N}_{k_{D-1}}
\end{bmatrix},
\]

(73)

where

\[
\tilde{N}_{e_I} := \begin{bmatrix}
0 & 0 & 0 \\
(2 - 2k_I + \epsilon_I)^2 & 2(2 - 2k_I + \epsilon_I) & 0 \\
0 & 0 & -1
\end{bmatrix},
\]

(74)

which are independent of \( t \). From \( \tilde{\mathcal{V}} > 0 \), we have a regularity condition \( 1/2 < k_I < 5/6 \). Note that the choice for \( \alpha_{IJ} \) (71) is to eliminate the leading order terms in the RSH system (72) obtained after using the solutions (69) and (70).

The procedure of replacement \( (t \partial_\theta \pi_{0l} \leftrightarrow \pi_{2l}, t \partial_\theta \kappa_{0l} \leftrightarrow \kappa_{2l}) \) is the same with one of the low velocity case (Subsection 5.2.2). Thus, we have the following result:

**Theorem 7** Suppose that \( p_{IA} \) and \( q_{IA} \) are smooth functions of \( \theta \) and \( 1/2 < k_I < 5/6 \) for all \( \theta \). Then, for each spatial point \( \theta = \theta_0 \), there exists a solution of the Einstein equations (50) and (51) in a neighborhood of \( \theta = \theta_0 \) of the form (69) and (70) where \( 2(k_I + k_J) - 3 < \epsilon_J < \min(2k_I - 1, 2 - 2k_I) \) for any \( I \) and \( J \), and \( \pi_I \) and \( \kappa_I \) are regular and tend to 0 as \( t \to 0 \). Given the form of the expansion and a choice of \( \epsilon_I \), the solution is unique. □
Remark 1  It is impossible to cover the whole range \(0 < k_I < 1\) in the analytic case (Theorem 4) by Theorem 6 and Theorem 7, which are of smooth cases. Fortunately, we can overcome this problem by repeating the above method \(n\) times. The argument is the same with Section 5.7 of [SF], so the details will be omitted. If solutions (69) are replaced by

\[ P_I(t, \theta) = P_I^{VTD} + \sum_{j=1}^{n} \alpha_{Ij}(\theta)t^{(2-2k_I)j} + t^{(2-2k_I)n+\epsilon} \pi_I(t, \theta), \tag{75} \]

the regularity condition of the right-hand-side of the symmetric hyperbolic system becomes

\[ 1 - 2[(n+1) - (k_I + nk_J)] < \epsilon_J < \min\{1 - 2n(1-k_I), 2 - 2k_I\}, \tag{76} \]

for any \(I\) and \(J\). Here, each \(\alpha_{Ij}\) is defined as the leading order terms are canceled at each stage like (71). Therefore, the number of free functions remain \(4 \times (D-3)\) still. Then, we have the following inequality for \(k_I\):

\[ 1 - \frac{1}{2n} < k_I < 1 - \frac{1}{2(n+2)}. \tag{77} \]

Thus, the range \((1/2, 1)\) is covered by the infinite sequence of intervals \((1 - 1/(2n), 1 - 1/(2(n+2)))\).

By combining this result with Theorem 6, an existence theorem of smooth AVTD solutions under the condition \(0 < k_I < 1\) is shown. \(\Box\)

6 Conclusion

We would like to comment on the structure of the spacetime into the future direction since we have not discussed on it. From point of view of the SCC, we want to show future completeness of any causal geodesic of the spacetime. Recently, it has been shown that Gowdy and \(U(1)\)-symmetric (in the case of small initial data) spacetimes are geodesically future complete [CB, CBC, CBM01, RH]. One of key ingredients is to show energy decay by using corrected energy method. Fortunately, estimate of energy decay for our wave map can be shown [NM04]. Another ingredient is the geometric structure of target spaces. Unfortunately, our understanding of the structure of (35) is entirely out of reach at the present time.

Acknowledgments

I am grateful to Lars Andersson, Alan Rendall and Yoshio Tsutsumi for commenting on the manuscript.
