The Relation Between
Second-Order Unification and
Simultaneous Rigid $E$-Unification

Acknowledgements

I thank Andrei Voronkov for many valuable discussions and for suggesting me to study the connections between second-order unification and simultaneous rigid $E$-unification, that ultimately led to this report. I thank Harald Ganzinger and Sergei Vorobyov for many valuable discussions and comments on earlier versions of this report.
Abstract

Simultaneous rigid $E$-unification, or SREU for short, is a fundamental problem that arises in global methods of automated theorem proving in classical logic with equality. In order to do proof search in intuitionistic logic with equality one has to handle SREU. Furthermore, restricted forms of SREU are strongly related to word equations and finite tree automata. Higher-order unification has applications in proof theory, computational linguistics, program transformation, and also in theorem proving. It was recently shown that second-order unification has a very natural reduction to simultaneous rigid $E$-unification, which constituted probably the most transparent undecidability proof of SREU. Here we show that there is also a natural encoding of SREU in second-order unification. It follows that the problems are logspace equivalent. We exploit this connection and use finite tree automata techniques to prove that second-order unification is undecidable in more restricted cases than known before. We present a more elementary undecidability proof of second-order unification than the previously known proofs exposing that already a very small fragment of second-order unification has the universal computational power.

Keywords

Second-order unification, simultaneous rigid $E$-unification, finite tree automata.
1 Introduction

Simultaneous Rigid E-Unification, or SREU for short, is originally introduced in 1987 by Gallier, Raatz, and Snyder [15] as a fundamental problem that arises in global or rigid-variable methods of automated theorem proving in classical logic with equality. For example, in free variable tableau methods, SREU corresponds to the problem of deciding if some substitution closes a given set of branches. In intuitionistic logic with equality, proof search leads to SREU. It is shown in Voronkov [33] that SREU is actually polynomial-time equivalent to skeleton instantiation (the problem of deciding if there is a proof with a given proof skeleton) in certain proof systems in intuitionistic logic with equality. There is a list of several fundamental decision problems in both classical and intuitionistic logic with equality that are very closely related to SREU [5].

The undecidability of SREU is shown in 1995 by Degtyarev and Voronkov [8]. Probably the most transparent undecidability proof of SREU [7, 10] is by reduction from second-order unification, proved undecidable in Goldfarb [17]. This reduction shows that any semidecision algorithm for SREU can be adapted to second-order unification. It was observed by the author and Voronkov that this connection should be studied further, in particular that the techniques used to prove some undecidability results of SREU [26, 29], could probably be adapted in the context of second-order unification. By using a recent construction from Levy [22], we present two lemmas in Section 3 that enable us to transfer techniques from the context of SREU to the context of SOU. The first application of these lemmas is the following result in Section 4, by using a restricted form of SREU [18].

*SREU and second-order unification are logspace equivalent.*

The general content of this result is that second-order unification plays the same fundamental role as SREU in logic with equality. For example, it implies that it is necessary to handle second-order unification in order to do proof search in intuitionistic logic with equality. From the viewpoint of automated theorem proving or proof search this connection is important because currently there are no known reasonable semidecision algorithms for SREU, except for ones based of straightforward enumeration [25]. The reduction to higher-order unification may provide new insights into how to deal with this.

By using a recent undecidability of a very restricted case of SREU [18], we obtain the following statement, that strengthens the result in Levy [22] with the last two conditions:
Second-order unification is undecidable with the following restrictions on equation systems $S$:

1. each second-order variable occurs at most twice in $S$,
2. there are at most 3 second-order variables in $S$,
3. there are at most 2 first-order variables in $S$.

There are many known relationships between SREU and intuitionistic logic [9, 31, 32], finite tree automata [16] and SREU [3, 4, 30], word equations [23] and monadic SREU [6, 19], word equations and monadic second-order unification [12], and there are connections between other restricted forms of second-order unification [21] and context-unification [27]. In Section 5 we exploit some of these connections and the lemmas in Section 3 to give a new elementary undecidability proof of second-order unification. In particular, we apply finite tree automata techniques in combination with encoding techniques involving valid Turing machine computations underlying the proofs in [18, 31]. To be precise, we construct (effectively) a universal second-order equation $S^u(x, F, G)$ of the form

$$g(F(\tilde{t}_1), G(\tilde{t}_2)) \approx g(f(x, F(\tilde{t}_3)), g(F(\tilde{t}_4), G(\tilde{t}_5)))$$

where all the $\tilde{t}_i$'s are sequences of ground terms of depth $\leq 1$ over a signature $\Sigma_u$, and $F$ and $G$ are second-order variables with matching arities, such that the following decision problem is undecidable:

Given a ground term $s$, is $S^u(s, F, G)$ solvable?

The construction of the universal second-order equation is relatively short and involves two steps that are intuitively clear. We can conclude the following.

Second-order unification is undecidable with the following restrictions on equation systems $S$:

1. there are no first-order variables in $S$,
2. at most two variables in $S$,
3. at most five occurrences of variables in $S$,
4. all occurrences of variables in $S$ have ground arguments, and
5. all arguments of variables have depth $\leq k$ for some fixed $k \geq 1$. 

2
By applying certain encoding techniques in Farmer [13], we prove in Section 6 that a signature consisting of one constant and one binary function symbol is already enough to obtain undecidability, without violating the above restrictions. Hence, our result implies the following complement to Farmer's undecidability theorem:

There is an integer \( n \) such that for all nonmonadic second-order languages with at least two second-order variables with arities \( \geq n \) the unification problem is undecidable already if there are at most five variable occurrences all having ground arguments of depth \( \leq n \).

The value of \( n \) is any integer greater than the maximum of the arities of \( F \) and \( G \) (in the universal second-order equation) and the value of \( k \). Moreover, it seems that the use of two second-order variables is necessary to obtain undecidability, e.g., the problem is decidable if there is just one second-order variable and it occurs at most twice [22].

Our result also confirms the statement in Schubert [28] that the undecidability of second-order unification holds for systems of equations where all variables have ground arguments, and improves it with the conditions (1–3) and (5). Allowing variables to occur in arguments of second-order variables is essential in Goldfarb's proof [17]. We note that the proof by Schubert involves a very complicated reduction from Minsky machines and appears to have some gaps. The undecidability of second-order unification for equations where all variables have ground arguments is used in Schubert [28] to derive the undecidability of a certain type inference problem.\(^1\)

2 Preliminaries

We assume that the reader is familiar with the notions of (first-order) terms, equations, substitutions, and standard notions related to first-order logic. We define the corresponding second-order notions without using an explicit variable binding operator like \( \lambda \), following Farmer [13] or Goldfarb [17].

A signature \( \Sigma \) is a collection of function symbols with fixed arities \( \geq 0 \) and, unless otherwise stated, \( \Sigma \) is assumed to contain at least one constant or function symbol with arity 0. We use \( (a, b, c, d, a_1, \ldots) \) for constants and \( (f, g, f_1, \ldots) \) for function symbols in general. A designated constant in \( \Sigma \) is denoted by \( c_\Sigma \).

\(^1\)Schubert shows the undecidability of the following decision problem for the Church-style system \( F \) [1]: Given a term \( t \), does there exist a base \( \Gamma \) and a type \( \tau \) such that \( \Gamma \vdash t : \tau \) is correct in the system \( F \)?
A term language or simply language is a triple $L = (\Sigma_L, \mathcal{X}_L, \mathcal{F}_L)$ of pairwise disjoint sets of symbols, where

- $\Sigma_L$ is a signature,
- $\mathcal{X}_L (x, y, x_1, y_1, \ldots)$ is a collection of first-order variables, and
- $\mathcal{F}_L (F, G, F_1, F', \ldots)$ is a collection of symbols with fixed arities $\geq 1$, called second-order variables.

Let $L$ be a language. $L$ is first-order, if $\mathcal{F}_L$ is empty; $L$ is second-order, otherwise. If $L$ is first-order then we write it as the pair $(\Sigma_L, \mathcal{X}_L)$. $L$ is monadic if all function symbols in $\Sigma_L$ have arity $\leq 1$. We use $(\nu, \nu_1, \ldots)$ to denote arbitrary variables in $L$, i.e., symbols in $\mathcal{X}_L \cup \mathcal{F}_L$. A language $L_1$ is an expansion of a language $L$, in symbols $L_1 \supseteq L$ or $L \subseteq L_1$, if $\Sigma_L \subseteq \Sigma_{L_1}$, $\mathcal{X}_L \subseteq \mathcal{X}_{L_1}$, and $\mathcal{F}_L \subseteq \mathcal{F}_{L_1}$.

The set of all terms in a language $L$, or $L$-terms, is denoted by $T_L$ and is defined as the set of all terms in the first-order language $(\Sigma_L \cup \mathcal{F}_L, \mathcal{X}_L)$. We use $(s, t, l, r, s_1, \ldots)$ for terms. We usually omit mentioning $L$ when it is clear from the context. The depth of a term is defined as usual, by letting the depth of a constant or first-order variable be 0 and the depth of a compound term be 1 plus the maximum of the depths of its immediate subterms. A ground term is one that contains no variables. The set of all ground terms in a language $L$ is denoted by $T_{\Sigma_L}$. Given a term $F(t)$, where $F$ is a second-order variable with arity $m$ and $t$ is a sequence of $m$ terms, the elements of $t$ are called the arguments of $F$. A (second-order) term is called simple if there are no nested occurrences of variables in it, i.e., all occurrences of second-order variables have ground arguments.

An equation in $L$ is an unordered pair of $L$-terms, denoted by $s \approx t$. Equations are denoted by $(e, e_1, \ldots)$. A rule in $L$ is an ordered pair of $L$-terms, denoted by $s \rightarrow t$. An equation or a rule is ground (simple) if the terms in it are ground (simple). The depth of an equation $s \approx t$ is the maximum of the depths of $s$ and $t$. A system of rules or equations is a finite set of rules or equations. Let $R$ be a system of ground rules, and $s$ and $t$ two ground terms. Then $s$ rewrites (in $R$) to $t$, denoted by $s \rightarrow_R t$, if $t$ is obtained from $s$ by replacing an occurrence of a term $l$ in $s$ by a term $r$ for some rule $l \rightarrow r$ in $R$. The term $s$ reduces (in $R$) to $t$, denoted by $s \rightarrow^* R t$, if either $s = t$ or $s$ rewrites to a term that reduces to $t$. We assume that the reader is familiar with the basic concepts in ground rewriting [11].

\footnote{By rules we understand thus directed equations. Only ground instantiations of rules are considered as rewrite rules}
2.1 Second-Order Unification

Given a language $L$, we need expressions representing functions that produce instances of terms in $L$. For that purpose we introduce an expansion $L^*$ of $L$. We follow Goldfarb [17] and Farmer [13]. Let $\{z_i\}_{i \geq 1}$ be an infinite collection of new symbols not in $L$. The language $L^*$ differs from $L$ by having $\{z_i\}_{i \geq 1}$ as additional first-order variables, called bound variables. The rank of a term $t$ in $L^*$, is either $0$ if $t$ contains no bound variables (i.e., $t \in T_L$), or the largest $n$ such that $z_n$ occurs in $t$. Given terms $t$ and $t_1, t_2, \ldots, t_n$ in $L^*$, we write $t[t_1, t_2, \ldots, t_n]$ for the term that results from $t$ by simultaneously replacing $z_i$ in it by $t_i$ for $1 \leq i \leq n$. An $L^*$-term is called closed if it contains no variables other than bound variables. Note that closed $L^*$-terms of rank $0$ are ground $L$-terms.

A substitution in $L$ is a function $\theta$ with finite domain $\text{dom}(\theta) \subseteq X_L \cup F_L$ that maps first-order variables to $L$-terms, and $n$-ary second-order variables to $L^*$-terms of rank $\leq n$. A substitution $\theta$ with domain $\{\nu_i \mid 1 \leq i \leq n\}$ such that $\theta(\nu_i) = t_i$ for $1 \leq i \leq n$, is also denoted by $\{\nu_i \mapsto t_i \mid 1 \leq i \leq n\}$. The result of applying a substitution $\theta$ to an $L$-term $s$, denoted by $s\theta$, is defined by induction on $s$:

1. If $s = x$ and $x \in \text{dom}(\theta)$ then $s\theta = \theta(x)$.
2. If $s = x$ and $x \notin \text{dom}(\theta)$ then $s\theta = x$.
3. If $s = F(t_1, \ldots, t_n)$ and $F \in \text{dom}(\theta)$ then $s\theta = \theta(F)[t_1\theta, \ldots, t_n\theta]$.
4. If $s = F(t_1, \ldots, t_n)$ and $F \notin \text{dom}(\theta)$ then $s\theta = F(t_1\theta, \ldots, t_n\theta)$.
5. If $s = f(t_1, \ldots, t_n)$ then $s\theta = f(t_1\theta, \ldots, t_n\theta)$.

We write also $F\theta$ for $\theta(F)$, where $F$ is a second-order variable. A substitution is called closed, if its range is a set of closed terms. Given a term $t$, a substitution $\theta$ is said to be grounding for $t$ if $t\theta$ is ground, similarly for other $L$-expressions. Given a sequence $\bar{t} = t_1, \ldots, t_n$ of terms, we write $\bar{t}\theta$ for $t_1\theta, \ldots, t_n\theta$.

Let $E$ be a system of equations in $L$. A unifier of $E$ is a substitution $\theta$ (in $L$) such that $s\theta = t\theta$ for all equations $s \approx t$ in $E$. $E$ is unifiable if there exists a unifier of $E$. Note that if $E$ is unifiable then it has a closed unifier that is grounding for $E$, since $T_{E_L}$ is nonempty. The unification problem for $L$ is the problem of deciding whether a given equation system in $L$ is unifiable. In general, the second-order unification problem or SOU is the unification problem for arbitrary second-order languages. Monadic SOU is SOU for monadic second-order languages.
2.2 Simultaneous Rigid $E$-Unification

In the following let $L$ be a first-order language. Given a system of equations $E$ in $L$ and an equation $e$ in $L$, the expression $E \vdash e$ is called a rigid equation in $L$, where $E$ is called the left-hand side of $E \vdash e$. A rigid equation $E \vdash e$ is solvable if there exists a substitution $\theta$ that is grounding for $E$ and $e$ such that $e\theta$ is a logical consequence of $E\theta$, such a substitution is said to solve the rigid equation. Rigid $E$-unification is the problem of deciding if a given rigid equation is solvable.

A system or finite set of rigid equations is solvable, if there exists a substitution that solves each rigid equation in that system. Simultaneous rigid $E$-unification for $L$ or SREU for $L$ is the problem of deciding if a given system of rigid equations in $L$ is solvable. In general, by SREU we mean SREU for arbitrary first-order languages. Monadic SREU is SREU for monadic first-order languages.

3 Relations between rewriting and second-order unification

In this section we present two lemmas that show a close relationship between certain forms of rewriting and second-order unification. These lemmas are used as basic tools in the following sections. The main statement is Lemma 1, that is inspired by the proof of the main lemma in Levy [22] and is used to derive a strengthened version of the latter (Lemma 2) with analogous proof. The basic techniques that are involved in these constructions appear already in Farmer [13] and Goldfarb [17].

We frequently need to refer to certain conditions on a sequence of parameters. In order to avoid lengthy repetitions of such conditions we use the following definition. We say that a parameter sequence

$$(L, c, f, F, m, L_1, s, t, \bar{l}, \bar{r})$$

is appropriate if the following conditions hold:

- $L$ is a language;
- $c$ is a constant, $f$ is a binary function symbol, and $f, c \notin \Sigma_L$;
- $F$ is a second-order variable with arity $m + 1$, $m \geq 0$, $F \notin \mathcal{F}_L$;
- $L_1 \supseteq (\Sigma_L \cup \{f, c\}, \mathcal{X}_L, \mathcal{F}_L \cup \{F\})$;
Given appropriate \((L, c, f, F, m, L_1, s, t, \vec{l}, \vec{r})\), we use the following construction from Levy [22]. Let \(SOE(c, f, F, s, t, \vec{l}, \vec{r})\) denote the following second-order equation in \(L_1\):

\[
SOE(c, f, F, s, t, \vec{l}, \vec{r}) = F(\vec{l}, f(s, c)) \approx f(t, F(\vec{r}, c)).
\]

Note that the sequences \(\vec{l}\) and \(\vec{r}\) are empty when \(m = 0\).

**Lemma 1** Let \((L, c, f, F, m, L_1, s, t, \vec{l}, \vec{r})\) be appropriate. The following statements are equivalent for all \(\theta\) in \(L_1\) such that \(\vec{\theta}, s\theta \in \mathcal{F}_{L_1}\).

(i) \(\theta\) solves \(SOE(c, f, F, s, t, \vec{l}, \vec{r})\), i.e., \(F(\vec{l}, f(s, c)) = f(t\theta, F(\vec{r}, c))\).

(ii) Either \(t\theta = s\theta\) and \(F\theta = z_{m+1}\), or there exists \(k \geq 1\) and closed \(L^*\)-terms \(s_i\) of rank \(\leq m\) for \(1 \leq i \leq k\), such that

\[
F\theta = f(s_1, f(s_2, \ldots, f(s_k, z_{m+1}) \cdots)) \tag{1}
\]

and

\[
t\theta = s_1[\vec{\theta}], \tag{2}
\]
\[
s_i[\vec{\theta}] = s_{i+1}[\vec{\theta}], \quad \text{for } 1 \leq i < k, \tag{3}
\]
\[
s_k[\vec{\theta}] = s\theta. \tag{4}
\]

**Proof.**

(i)\(\iff\) (ii) Straightforward.

(i)\(\implies\) (ii) Let \(\theta\) satisfying (i) be given. Say that an \(L^*_1\)-term \(t'\) is a list if either \(t' = z_{m+1}\), or \(t' = f(t_1, t_2)\) for some \(t_1\) and \(t_2\), where \(t_2\) is a list. We use the following statement to show that \(F\theta\) is a list:

(*) For all \(L^*_1\)-terms \(t_1\) and \(t_2\), if

\[
t_2[\vec{\theta}, f(s\theta, c)] = f(t_1, t_2[\vec{\theta}, c]) \tag{5}
\]

then \(t_2\) is a list.
Proof. By induction on the number of symbols in \( t_2 \).

Assume that \( t_2 \) is either a constant, a variable in \( X_L \), or a bound variable. If (5) holds then the head symbol of the left-hand side of (5) must be \( f \). The only possibility is \( t_2 = z_{m+1} \) because \( \tilde{\theta} \in T_{\Sigma_L} \) and \( f \notin \Sigma_L \).

Assume now that \( t_2 \) is a compound term and (5) holds. Then the head symbol of \( t_2 \) must be \( f \). So \( t_2 = f(t_{21}, t_{22}) \) for some \( L_1 \)-terms \( t_{21} \) and \( t_{22} \). Hence, by (5),

\[
f(t_{21}, t_{22})[\tilde{\theta}, f(s\theta, c)] = f(t_1, f(t_{21}, t_{22})[\tilde{\theta}, c]),
\]

and thus

\[
t_{22}[\tilde{\theta}, f(s\theta, c)] = f(t_{21}[\tilde{\theta}, c], t_{22}[\tilde{\theta}, c]).
\]

By the induction hypothesis \( t_{22} \) is a list and hence so is \( t_2 \). \( \square \)

We know that \( F\theta \) is an \( L_1 \)-term of rank \( m + 1 \). It follows from \((\ast)\) and (i) that \( F\theta \) is a list. If \( F\theta = z_{m+1} \) then (i) implies that \( s\theta = t\theta \), and thus (ii) holds. Assume that \( F\theta \neq z_{m+1} \), i.e., there exists \( k \geq 1 \) and \( L_1 \)-terms \( s_i \) (of rank \( \leq m + 1 \)) for \( 1 \leq i \leq k \), such that

\[
F\theta = f(s_1, f(s_2, \ldots, f(s_k, z_{m+1}) \ldots)).
\]

We show that each \( s_i \) is a closed \( L \)-term of rank \( \leq m \), such that (2-4) hold. It follows from (i) that

\[
f(s_1[\tilde{\theta}, s'], \ldots, f(s_{i+1}[\tilde{\theta}, s'], \ldots, f(s\theta, c)\ldots) = f(t\theta, \ldots, f(s_i[\tilde{\theta}, c], \ldots, f(s_k[\tilde{\theta}, c], \ldots), \ldots),
\]

where \( s' = f(s\theta, c) \). Hence, \( s_i[\tilde{\theta}, s'] = t\theta, s_{i+1}[\tilde{\theta}, s'] = s_i[\tilde{\theta}, c] \) for \( 1 \leq i < k \), and \( s\theta = s_k[\tilde{\theta}, c] \). So, \( s_k \) is a closed \( L \)-term of rank \( \leq m \) since \( s\theta \) is a ground \( L \)-term and \( c \) is not in \( L \) (recall that \( \tilde{\theta} \) is a sequence of \( m \) terms), and thus (4) holds. We prove by induction on \( k = i \) that each \( s_i \) is a closed \( L \)-term of rank \( \leq m \). The base case is \( i = k \). Assume the statement is true for \( i + 1 \leq k \), we prove it for \( i \). Then \( s_{i+1}[\tilde{\theta}, s'] = s_{i+1}[\tilde{\theta}] \) is a ground \( L \)-term since \( \tilde{\theta} \) are ground \( L \)-terms, and by above, so is \( s_i[\tilde{\theta}, c] \). Hence, \( s_i \) is a closed \( L \)-term of rank \( \leq m \), since \( c \) is not in \( L \). The conditions (2) and (3) follow. \( \square \)

Lemma 2 Let \( (L, c, f, F, m, L_1, s, t, \overline{t}, \overline{r}) \) be appropriate. The following statements are equivalent for all \( \theta \) in \( L_1 \) such that \( F \notin \text{dom}(\theta) \) and \( s\theta, \tilde{\theta}, \tilde{r} \in T_{\Sigma_L} \).

(i) \( \theta \cup \{ F \mapsto t' \} \) solves \( \text{SOE}(c, f, s, t, \overline{t}, \overline{r}) \) for some \( t' \).

(ii) \( (t\theta \in T_{\Sigma_L} \text{ and } t\theta \xrightarrow{s_\theta} \{ t_i, \theta \mapsto t_i, 1 \leq i \leq m \}) \).

Proof.
\[ ((i) \Rightarrow (ii)) \] Let \( \theta' = \theta \cup \{ F \mapsto t' \} \) satisfying (i) be given. There are two cases by Lemma 1((i)⇒(ii)). First case is \( t' = z_{m+1} \) and \( t\theta' = s\theta' \), and thus \( t\theta = s\theta \) (since \( s, t \in T_L \) and \( F \notin F_L \)), and hence (ii) holds trivially. The second case is that there exists \( k \geq 1 \) and closed \( L^* \)-terms \( s_i \) of rank \( \leq m \) for \( 1 \leq i \leq k \), such that

\[ t' = f(s_1, f(s_2, \ldots, f(s_k, z_{m+1}) \cdots)) \]

and \( t\theta = s_1[\overline{\theta}], s_i[\overline{\theta}] = s_{i+1}[\overline{\theta}] \), for \( 1 \leq i < k \), \( s_k[\overline{\theta}] = s\theta \), where we have correctly inserted \( \theta \) for \( \theta' \) since \( s, t, \overline{t}, \overline{r} \in T_L \) and \( F \notin F_L \). Let \( R \) be the following system of ground rules in \( L^* \):

\[ R = \{ l_i \theta \rightarrow r_i \theta \mid 1 \leq i \leq m \} \]

Clearly, \( s_i[\overline{\theta}] \xrightarrow{s} R s_{i+1}[\overline{\theta}] \) for \( 1 \leq i < k \), and thus \( s_i[\overline{\theta}] \xrightarrow{s} R s_{i+1}[\overline{\theta}] \), for \( 1 \leq i < k \), by above. It follows that

\[ t\theta = s_1[\overline{\theta}] \xrightarrow{s} R s_k[\overline{\theta}] \xrightarrow{s} R s_k[\overline{\theta}] = s\theta, \]

as needed.

\[ ((ii) \Rightarrow (i)) \] Let \( \theta \) satisfying (ii) be given and \( R = \{ l_i \theta \rightarrow r_i \theta \mid 1 \leq i \leq m \} \). We have a reduction:

\[ t\theta \rightarrow t_0 \rightarrow R t_1 \rightarrow R \cdots \rightarrow R t_{k-1} \rightarrow R t_k = s\theta. \]

If \( k = 0 \) then let \( t' = z_{m+1} \) and (i) follows from Lemma 1((ii)⇒(i)). Assume that \( k \geq 1 \) and consider a fixed \( i, 1 \leq i \leq k \). The rewrite step \( t_{i-1} \rightarrow R t_i \) uses a rule \( l_j \theta \rightarrow r_j \theta \) for some \( j, 1 \leq j \leq m \), and replaces a certain subterm occurrence of \( l_j \theta \) in \( t_{i-1} \) by \( r_j \theta \). Construct \( s_i \) from \( t_{i-1} \) by replacing that occurrence by \( z_j \). Thus \( s_i[\overline{\theta}] = t_{i-1} \) and \( s_i[\overline{\theta}] = t_i \). Given such \( s_i \) for \( 1 \leq i \leq k \), obviously (2-4) are true. Let \( t' \) be the term above. Statement (i) follows from Lemma 1((ii)⇒(i)).

4 Reduction of SREU to SOU

In this section we show that there is a logspace reduction of SREU to SOU. The converse reduction, from SOU to SREU, is given in Degtyarev and Voronkov [7, 10] and is also logspace. We use a restricted form of SREU that is logspace equivalent with SREU and allows us to apply Lemma 2 in a direct manner.
Let \( L \) be a first-order language and \( \mathcal{R} \) a system of rigid equations in \( L \) and let \( L_1 \) be an arbitrary expansion of \( L \). The following property for systems of rigid equations guarantees that any substitution \( \theta \) in \( L_1 \) that solves \( \mathcal{R} \), maps variables occurring in \( \mathcal{R} \) to ground terms in \( L \). Let \( x \) be a variable that occurs in \( \mathcal{R} \). A guard for \( x \) in \( \mathcal{R} \), if one exists, is any rigid equation
\[
E \models \psi \ s \approx \ t \ 	ext{in} \ \mathcal{R} \ 	ext{such that}
\]
- \( E \) is a set of ground equations,
- \( s \) is a ground term, and
- \( x \) occurs in \( t \).

The system \( \mathcal{R} \) is called guarded if there is a guard in \( \mathcal{R} \) for each variable that occurs in \( \mathcal{R} \). Guarded SREU is SREU restricted to guarded systems of rigid equations. The notion of guardedness is introduced in Gurevich and Veanes [18].

**Lemma 3** SREU is logspace equivalent to guarded SREU.

**Proof.** Let \( \mathcal{R} \) be a system of rigid equations and \( \Sigma \) the set of function symbols in \( \mathcal{R} \) expanded with an additional constant if there is no constant in \( \mathcal{R} \). Let \( \mathcal{X} \) be the set of variables in \( \mathcal{R} \) and let \( L = (\Sigma, \mathcal{X}) \). For each variable \( x \) in \( \mathcal{X} \), for which there is no guard in \( \mathcal{R} \), construct the following rigid equation:
\[
|\text{Gr}(\Sigma, x) = \{ f(c_{\Sigma}, \ldots, c_{\Sigma}) \approx c_{\Sigma} \mid f \in \Sigma \setminus \{c_{\Sigma}\} \} \models \psi \ c_{\Sigma} \approx x. |
\]

Let \( \mathcal{R}' \) be the extension of \( \mathcal{R} \) with such rigid equations. Obviously is \( \mathcal{R}' \) guarded. It is straightforward to prove that for all substitutions \( \theta, \vartheta \) solves \( \text{Gr}(\Sigma, x) \) if and only if \( x\theta \in T_{\Sigma} \) [10, Lemma 3]. Hence, for all substitutions \( \theta \) in \( L \), \( \theta \) solves \( \mathcal{R} \) if and only if \( \theta \) solves \( \mathcal{R}' \).

The following result is implied by the reduction in Degtyarev and Voronkov [10].

**Theorem 1 (Degtyarev-Voronkov [10])** There is a logspace reduction of SOU to SREU.

\[\text{Note that } f(c_{\Sigma}, \ldots, c_{\Sigma}) \text{ stands for } f \text{ when } f \text{ has arity 0, it stands for } f(c_{\Sigma}) \text{ when } f \text{ has arity 1, and so on.}\]

\[\text{Personal communication with Voronkov.}\]
We use the following definitions. Let $L$ be a first-order language and $\mathcal{R}$ a system of rigid equations in $L$. For an equation system $E$ in $L$ we write $R_E$ for the following set of rules in $L$:

$$R_E = \{ s \to t, t \to s \mid s \approx t \in E \}.$$ 

Let $\mathcal{F}_R$ denote the following set of distinct second-order variables:

$$\mathcal{F}_R = \{ F_{E_{\forall \psi}} \text{ of arity } |R_E| + 1 \mid E \vdash \psi \in \mathcal{R} \}.$$

Let $f_\mathcal{R}$ be a binary function symbol and $c_\mathcal{R}$ a constant that are not in $L$. We write $L_\mathcal{R}$ for the following expansion of $L$:

$$L_\mathcal{R} = (\Sigma_L \cup \{ f_\mathcal{R}, c_\mathcal{R} \}, \lambda_L, \mathcal{F}_R).$$

For each rigid equation $E \vdash \psi s \approx t$ in $\mathcal{R}$, consider a fixed enumeration

$$\{ l_i \to r_i \mid 1 \leq i \leq |R_E| \} = R_E$$

and let $\vec{l} = l_1, l_2, \ldots, l_{|R_E|}$ and $\vec{r} = r_1, r_2, \ldots, r_{|R_E|}$. It is easy to check that

$$(L, c_\mathcal{R}, f_\mathcal{R}, F_{E_{\forall \psi \exists \xi}}, |R_E|, L_\mathcal{R}, s, t, \vec{r})$$

is appropriate. Define

$$SOE(\mathcal{R}, E \vdash \psi s \approx t) = SOE(c_\mathcal{R}, f_\mathcal{R}, F_{E_{\forall \psi \exists \xi}}, s, t, \vec{r}),$$

and

$$SOE(\mathcal{R}) = \{ SOE(\mathcal{R}, E \vdash \psi s \approx t) \mid E \vdash \psi s \approx t \in \mathcal{R} \}.$$ 

The construction corresponding to $SOE(\mathcal{R})$ is applied in Levy [22] to a variant of SREU called simultaneous ground rigid $O$-unification that disallows equations of the form $t \approx x$, where $x$ is a variable, to appear in the left-hand side of rigid equations. The following example shows that the notion of guardedness is important also in this restricted case.

**Example 1** Consider the system $\mathcal{R} = \{ \emptyset \vdash \psi x = y \}$ where $x$ and $y$ are variables. Then $SOE(\mathcal{R})$ has the form $\{ F(f(x, c)) \approx f(y, F(c)) \}$. Let $\theta = \{ F \mapsto f(z_1, z_1), x \mapsto c, y \mapsto f(c, c) \}$. It is easy to check that $\theta$ solves $SOE(\mathcal{R})$ but it doesn’t solve $\mathcal{R}$.

**Theorem 2** Let $L$ be a first-order language and $\mathcal{R}$ a guarded system of rigid equations in $L$. The following statements are equivalent for all $\theta$ in $L_\mathcal{R}$ such that $\text{dom}(\theta) \cap \mathcal{F}_R = \emptyset$.

(i) Some extension of $\theta$ with $\mathcal{F}_R$ solves $SOE(\mathcal{R})$.

(ii) $\theta$ solves $\mathcal{R}$.

**Proof.** Let $L$, $\mathcal{R}$ and $\theta$ be given. Let $\mathcal{R} = \{ E_i \vdash \psi s_i \approx t_i \mid 1 \leq i \leq n \}$ and let us write $F_i$ for $F_{E_i \vdash \psi \exists \xi}$ and $R_i$ for $R_{E_i}$. The following holds by Birkhoff’s completeness theorem for all $i$, $1 \leq i \leq n$, assuming $\theta$ is grounding for $\mathcal{R}$:

$$\theta \text{ solves } E_i \vdash \psi s_i \approx t_i \iff t_i \theta \not\approx_{R_i \theta} s_i \theta. \quad (7)$$
Assume that $\theta' = \theta \cup \{ F_i \mapsto t'_i \mid 1 \leq i \leq n \}$ solves $\text{SOE}(\mathcal{R})$.

First we show that, for $1 \leq i \leq n$, $R_i \theta$ is a set of ground rules in $L$ and $s_i \theta$ is a ground term in $L$. Consider a fixed $i$. Let $x$ be a variable in $R_i$ or $s_i$. Let $E_j \vdash \forall s_j \approx t_j$ be a guard for $x$ in $\mathcal{R}$. So $R_j$ and $s_j$ are ground and $\theta \cup \{ F_j \mapsto t'_j \}$ solves $\text{SOE}(\mathcal{R}, E_j \vdash \forall s_j \approx t_j)$. Hence, it follows from Lemma 2((i)⇒(ii)) that $t_i \theta \in \mathcal{T}_{\Sigma_L}$. But $x \theta$ occurs in $t_i$, and thus $x \theta \in \mathcal{T}_{\Sigma_L}$.

Second, since $\theta \cup \{ F_i \mapsto t'_i \}$ solves $\text{SOE}(\mathcal{R}, E_i \vdash \forall s_i \approx t_i)$ and all the terms in $R_i \theta$ and $s_i \theta$ are in $\mathcal{T}_{\Sigma_L}$, it follows again from Lemma 2((i)⇒(ii)) that $t_i \theta \in \mathcal{T}_{\Sigma_L}$. Thus, it follows from (7) that $\theta$ solves $E_i \vdash \forall s_i \approx t_i$. Consequently $\theta$ solves $\mathcal{R}$.

Note that an analogous way to prove Theorem 2 when starting from an arbitrary system of of rigid equations $\mathcal{R}$ over a signature $\Sigma$, is to add the second-order equation corresponding to $\text{Gr}(\Sigma, x)$ (in Lemma 3), for each variable $x$ in $\mathcal{R}$ (that has no guard in $\mathcal{R}$), to the resulting system of second-order equations.

Clearly, the system $\text{SOE}(\mathcal{R})$ is just another representation of $\mathcal{R}$. It follows from Theorem 2 that any semidecision algorithm for SOU that also produces a solution if one exists, can directly be used as a semidecision procedure for guarded SREU that also produces a solution if one exists.

**Theorem 3** SREU is logspace equivalent to SOU.

**Proof.** By Lemma 3, Theorem 1, and Theorem 2. 

There is an important difference between the reduction from SREU to SOU on one hand and the reduction from SOU to SREU on the other hand. In the former reduction one needs a binary function symbol, whereas the latter reduction [7, 10] shows that monadic SOU reduces to monadic SREU. The use of the binary function symbol in the former reduction seems to be unavoidable because of the following reason. Decidability of monadic second-order unification can be proved by reduction to word equations [12], whereas monadic SREU is only known to reduce to a nontrivial extension of word equations [19]. The decidability of monadic SREU is currently an open problem, only some special cases are known to be decidable [19, 6]. The decidability of monadic SREU is equivalent to the decidability of the prenex fragment of intuitionistic logic with equality restricted to function symbols of arity $\leq 1$. A recent report by Voronkov discusses in detail the connections between SREU and other related problems [35].

12
Undecidability of a restricted case of SOU

The following theorem is a central result in Levy [22]. It is proved by reducing simultaneous ground rigid O-unification to SOU, by using a construction corresponding to $SOE(R)$ and noting that the reduction in Degtyarev and Voronkov [10] can be adapted to simultaneous ground rigid O-unification.

**Theorem 4 (Levy [22])** *SOU is undecidable when restricted to systems of equations such that each second-order variable occurs at most twice in the system.*

By using the following lemma (an immediate corollary of [18, Theorem 18]) and Theorem 2, we can conclude that Theorem 4 holds already with very strong restrictions on the number of variables.

**Lemma 4 (Gurevich-Veanes [18])** *Solvability of guarded systems of rigid equations with at most three rigid equations and at most two variables is undecidable.*

**Theorem 5** *SOU is undecidable when restricted to systems $S$ such that*

1. *each second-order variable occurs at most twice in $S$,*
2. *there are at most 3 second-order variables in $S$, and*
3. *there are at most 2 first-order variables in $S$.*

**Proof.** Let $R$ be a guarded system of three rigid equations with two variables. Then $SOE(R)$ is a system of second-order equations that satisfies the restrictions (1–3). By Theorem 2, $R$ is solvable if and only if $SOE(R)$ is solvable. The undecidability follows from Lemma 4.

We can note that the second-order equations that we obtain in Theorem 5 are not simple (even if we consider the most restricted case in [18]). In order to prove the undecidability of the other cases of SOU that are listed in the introduction we have to apply the techniques that underlie the proof of Lemma 4 directly in the context of second-order unification. We do this in Section 5. We note, however, that the main result in Section 5 is an independent result that does not imply Theorem 5, because the number of variable occurrences is violated. For example, the decidability of SOU restricted to 2 second-order variables, each occurring at most twice, remains an open problem. This case is strongly related to the decidability of SREU with 2 rigid-equations, which is also an open problem.
5  A new elementary undecidability proof of SOU

In this section we present a new elementary undecidability proof of SOU, that does not rely on the deep theory underlying the undecidability proof of Hilbert’s tenth problem due to Matiyasevich [24], that is used in Goldfarb [17]. As a corollary we can show the undecidability of SOU in more restricted cases than known previously. We adopt techniques from Gurevich and Veanes [18] and Veanes [30, 31], that originate from techniques in Plaisted [26], Goldfarb [17] and Hopcroft and Ullman [20, Lemma 8.6].

The undecidability proof is by reduction from the halting problem for Turing machines. We consider a fixed deterministic Turing machine $M$ with initial state $q_0$, final state $q_f$, a blank character $\mathbb{b}$, and an input alphabet that does not include the blank. By $\Sigma_M$ we denote the set of all the symbols in $M$, i.e., the states, the input characters and the blank. All elements of $\Sigma_M$ are assigned arity 0, i.e., are treated as constants. $M$ is allowed to write blanks, however, $M$ is only allowed to write a blank when it erases the last nonblank symbol on the tape and the tape head must move left after that. We assume, without loss of generality, that when $M$ enters the final state then its tape is empty.

An ID of $M$ is any string $vqw$ where $vw$ is a string over the input alphabet of $M$ and $q$ is a state of $M$. In particular, the initial ID of $M$ for input string $v$ has the form $q_0v$, and the final ID is simply the one character string $q_f$. A move of $M$ is any pair of strings $(v, v^+)$ where $v$ is an ID and $v^+$ is the successor of $v$ according to the transition function of $M$, if $v$ is nonfinal; $v^+$ is the empty string ($\epsilon$), otherwise (i.e., $q_f^+ = \epsilon$).

5.1 Main idea

We construct two second-order equations from $M$: $S_{m}^{M}(F,G)$ and $S_{sp}^{M}(x,F)$, that have roughly the following properties: (for any substitution $\theta$ such that $G \notin \text{dom}(\theta)$ and input string $v_0$ for $M$)

1. $\theta \cup \{G \mapsto t\}$ solves $S_{m}^{M}(F,G)$ (for some $t$) if and only if $F\theta$ represents a sequence of moves of $M$:
   $$((v_1, v_1^+), (v_2, v_2^+), \ldots, (v_k, v_k^+)).$$

2. $\theta$ solves $S_{sp}^{M}(q_0v_0, F)$ if and only if $F\theta$ represents the shifted pairing of a sequence of IDs $(v_1, v_2, \ldots, v_k)$ where $v_1 = q_0v_0$. (See Figure 1.)

Consequently, $\theta$ solves both second-order equations (for some $G\theta$) if and only if $F\theta$ represents a valid computation of $M$ with input $v_0$. 

14
5.2 Encoding sequences of moves

We introduce a family of new constants \( \{c_{ab}\}_{a,b \in \Sigma_M} \) and use them to encode moves of \( M \) in the following manner. Let \( v = a_1 a_2 \cdots a_m \) be any ID of \( M \) and let \( v^+ = b_1 b_2 \cdots b_n \). (Note that \( m - 1 \leq n \leq m + 1 \).) We let \( \langle v, v^+ \rangle \) denote the following string:

\[
\langle v, v^+ \rangle = \begin{cases} 
  c_{a_1 b_1} c_{a_2 b_2} \cdots c_{a_m b_m} c_{b_n}, & \text{if } n = m + 1; \\
  c_{a_1 b_1} c_{a_2 b_2} \cdots c_{a_n b_n} c_{a_m b_n}, & \text{if } n = m - 1; \\
  c_{a_1 b_1} c_{a_2 b_2} \cdots c_{a_m b_n}, & \text{if } n = m.
\end{cases}
\]

we call such a string a move also. (Note that \( \langle q, \epsilon \rangle = c_{q \epsilon} \).) Intuitively, a blank is added at the end of the shorter of the two strings (in case they differ in length) and the pair of the resulting strings is encoded character by character.

We fix two new constants \( c_w \) and \( c_t \) and two new binary function symbols \( f_w \) and \( f_t \), and let \( \Sigma_{id} \) and \( \Sigma_{mv} \) be the following signatures:

\[
\Sigma_{id} = \Sigma_M \cup \{c_w, f_w\}, \\
\Sigma_{mv} = \{c_{ab} \mid (a, b) \in \Sigma_M \times \Sigma_M \} \cup \{c_w, f_w, c_t, f_t\}.
\]

A term \( s \) is a called a word if either \( s = c_w \) (the empty word), or \( s = f_w(c, s') \) for some constant \( c \) that is distinct from \( c_w \) and word \( s' \). Whenever convenient, we write a word as the corresponding string surrounded by double quotes:

\[
\text{"} f_w(a_1, f_w(a_2, \ldots, f_w(a_n, c_w) \ldots)) \text{"} = "a_1 a_2 \cdots a_n",
\]

and say that the word represents the string. A term \( t \) is called a train, if either \( t = c_t \) (the empty train), or \( t = f_t(s, t') \) for some word \( s \) and train \( t' \). So trains are simply representations of string sequences. Conceptually we identify words with strings and trains with sequences of strings.

A train that represents a sequence of moves is called a move-train. The following lemma is used together with Lemma 2 to construct the second-order equation \( S_{mv}^M(F, G) \) with the desired properties.

**Lemma 5** There is a system \( R_{mv} \) of ground rules of depth \( \leq 1 \) over a signature \( \Sigma_{mv}^r \), where \( \Sigma_{mv} \subseteq \Sigma_{mv}^r \) and \( \Sigma_{mv} \setminus \Sigma_{mv}^r \) is a set of constants, such that, for all terms \( t \in T_{mv}^r \), \( t \) is a move-train if and only if \( t \leftarrow R_{mv} c_t \).
Proof. One can construct a deterministic finite bottom-up tree automaton (or DTA) that recognizes the set of all move-trains [18, 30, Train Theorem]. In particular, such a DTA can be constructed with one final state. When viewing DTAs as certain ground rewrite systems (see for example Dauchet [2]) then the rule set $R_{\text{mv}}$ is simply the rule set of that DTA. 

5.3 The main reduction
Throughout the rest of this section we use the following shorthand notation. Let $R_{\text{mv}}$ and $\Sigma'_{\text{mv}}$ be given by Lemma 5, such that $(\Sigma'_{\text{mv}} \setminus \Sigma_{\text{mv}}) \cap \Sigma_{\text{id}} = \emptyset$.

- $m = |\Sigma_M|^2$ and $(a_1, b_1), (a_2, b_2), \ldots, (a_m, b_m)$ is a fixed sequence of all the pairs in $\Sigma_M \times \Sigma_M$.
- $\bar{c} = c_{a_1b_1}, c_{a_2b_2}, \ldots, c_{a_mb_m}$, note that $\bar{c} \in T_{\Sigma_{\text{mv}}}$.
- $\bar{a} = a_1, a_2, \ldots, a_m$ and $\bar{t}_{\text{sp}} = \bar{a}, \text{"}\bar{a}\text{"}, c_w, \text{"}\bar{a}\text{"}$, note that $\bar{t}_{\text{sp}} \in T_{\Sigma_{\text{id}}}$.
- $\bar{b} = b_1, b_2, \ldots, b_m$ and $\bar{r}_{\text{sp}} = \bar{b}, c_w, \text{"}\bar{b}\text{"}, \text{"}\bar{b}\text{"}$, note that $\bar{r}_{\text{sp}} \in T_{\Sigma_{\text{id}}}$.
- $m_1 = m + 3$ and $F$ is a new second-order variable with arity $m_1 + 1$.
- Consider a fixed sequence of all the rules in $R_{\text{mv}}$. Let $l_{\text{mv}}$ be the corresponding sequence of all the left-hand sides, and $r_{\text{mv}}$ the corresponding sequence of all the right-hand sides. Note that $l_{\text{mv}}, r_{\text{mv}} \in T_{\Sigma'_{\text{mv}}}$.
- $m_2 = |R_{\text{mv}}|$ and $G$ is a new second-order variable with arity $m_2 + 1$.
- $L_{\text{id}} = (\Sigma_{\text{id}}, \emptyset, \emptyset)$.
- $L'_{\text{mv}} = (\Sigma'_{\text{mv}}, \emptyset, \{F\})$.
- $d$ is a new constant and $g$ is a new binary function symbol.
- $L$ is (any expansion of) $(\Sigma_{\text{id}} \cup \Sigma'_{\text{mv}} \cup \{d, g\} \cup \emptyset, \{F, G\})$.

We use the following facts without further notice:

- $(L_{\text{id}}, c_t, f_t, F, m_1, L, \text{"}\bar{c}\text{"}, t, \bar{t}_{\text{sp}}, \bar{r}_{\text{sp}})$ (for $t \in T_{\Sigma_{\text{id}}}$) is appropriate.
- $(L'_{\text{mv}}, d, g, G, m_2, L, c_t, F(\bar{c}, c_w, c_w, c_t), \bar{l}_{\text{mv}}, \bar{r}_{\text{mv}})$ is appropriate.
For $t \in T_{\Sigma}$, we define the second-order equations $S_{sp}^M(t, F)$ and $S_{mv}^M(F, G)$ and the system $S^M(t, F, G)$ in $L$ as follows:

\[
S_{sp}^M(t, F) = \text{SOE}(c_t, f_t, F, \tilde{t}, \tilde{r}_{sp}),
\]

\[
S_{mv}^M(F, G) = \text{SOE}(d, g, c_t, F(c, c_w, c_w, c), \tilde{r}_{mv}),
\]

\[
S^M(t, F, G) = \{S_{sp}^M(t, F), S_{mv}^M(F, G)\}.
\]

Let us briefly recall the intuition behind this construction. Assume that $\theta$ solves the system. To start with consider $S_{mv}^M(F\theta, G\theta)$. It follows from Lemma 5 (with a little help from Lemma 6 below) that $F\theta[c, c_w, c_w, c_1]$ is a term in $T_{\Sigma_{mv}}$ representing a sequence of moves:

\[(v_1, v_2^+, \ldots, v_k^+).
\]

Next consider $S_{mv}^M(t, F\theta)$ and Lemma 1, which tells us firstly that the function symbols in $F\theta$ are in $\Sigma_{id} \cup \{f_t\}$. So $F\theta$ cannot contain any symbols from $\tilde{c}$, because the only constant that $\Sigma_{id}$ and $\Sigma_{mv}$ have in common is the empty word. Consequently, $F\theta$ has the bound variable $z_i$ for every occurrence of $c_{a,b}$ in $F\theta[c, c_w, c_w, c_1]$. Therefore $F\theta[\tilde{r}_{sp}, f_t(\tilde{t}, c_1)]$ represents (roughly) the sequence:

\[(v_1, v_2, \ldots, v_k, \tilde{t}),
\]

and $F\theta[\tilde{r}_{sp}, c_1]$ represents (roughly) the sequence:

\[(v_1^+, v_2^+, \ldots, v_k^+),
\]

and the conditions (2–4) in Lemma 1 imply that $(v_1, v_2, \ldots, v_k)$ is a valid computation.

**Lemma 6** Let $t \in T_{\Sigma_{id}}$. If $\theta$ solves $S^M(t, F, G)$, then $F\theta[c, c_w, c_w, c_1] \in T_{\Sigma_{mv}}$.

**Proof.** Given $t \in T_{\Sigma_{id}}$ and $\theta$ in $L$, assume that $\theta$ solves $S^M(t, F, G)$. Then $\theta$ solves $S_{sp}^M(t, F)$. It follows from Lemma 1 that $F\theta$ is a closed $(\Sigma_{id} \cup \{f_t\}, \emptyset)$-term of rank $\leq m_1 + 1$. Since $\theta$ solves also $S_{mv}^M(F, G)$, Lemma 2 implies that $F\theta[c, c_w, c_w, c_1] \in T_{\Sigma_{mv}}$. The rest is obvious from the fact that $(\Sigma'_{mv} \setminus \Sigma_{mv}) \cap \Sigma_{id} = \emptyset$.

Given an input string $v$ for $M$, we let $S_v^M(F, G) = S^M(\tilde{v}, F, G)$. (Recall that $q_0v$ is the initial ID of $M$ with input $v$.) We can now prove the main theorem.

**Theorem 6** For any input string $v_0$ for $M$, $S_{v_0}^M(F, G)$ is solvable if and only if $M$ accepts $v_0$.

**Proof.** Let $v_0$ be an input string for $M$. 

17
Assume that $S^M_{v_0}(F, G)$ is solvable. Let $\theta$ be a substitution in $L$ that solves $S^M_{v_0}(F, G)$. Since $\theta$ solves $S^M_{v_0}(F, G)$, it follows from Lemma 2 that

$$F\theta[\overline{c}, c_w, c_w, c_w, c_t] \rightarrow^* \overline{r}_t.$$  

Hence, by Lemma 6 and Lemma 5, $F\theta[\overline{c}, c_w, c_w, c_w, c_t]$ is a move-train:

$$F\theta[\overline{c}, c_w, c_w, c_w, c_t] = f_1(\langle v_1, v_1^+ \rangle), f_1(\langle v_2, v_2^+ \rangle), \ldots, f_1(\langle v_k, v_k^+ \rangle, c_t) \cdots),$$  

where each $v_i$ is an ID of $M$ and $k \geq 0$. But $\theta$ solves also $S^M_{v_0}(\langle q_0v_0 \rangle, F)$. Hence, it follows from Lemma 1 that

$$F\theta = f_1(s_1, f_1(s_2, \ldots, f_1(s_k, z_{m+1}) \cdots)),$$  

where each $s_i$ is a closed $L^*_w$-term of rank $\leq m_1$ and $k \geq 1$. (The case $F\theta = z_{m+1}$, i.e., $k = 0$, is not possible because $\langle q_0v_0 \rangle \neq \langle b \rangle$.) Moreover,

$$\langle q_0v_0 \rangle = s_1[\overline{t}_{sp}],$$  

$$s_i[\overline{t}_{sp}] = s_{i+1}[\overline{t}_{sp}], \quad \text{for } 1 \leq i < k,$$  

$$s_k[\overline{t}_{sp}] = \langle b \rangle.$$  

It follows from (8), (9), and each $s_i$ having rank $\leq m_1$, that

$$s_i[\overline{c}, c_w, c_w, c_w] = \langle v_i, v_i^+ \rangle, \quad \text{for } 1 \leq i \leq k.$$  

Note that $s_i[\overline{c}, c_w, c_w, c_w] \in T_{v_0w}$ and $s_i[\overline{t}_{sp}], s_i[\overline{r}_{sp}] \in T_{v_0w}$ for $1 \leq i \leq k$. The only constant that can occur in any $s_i$ is therefore $c_w$.

In order to show that $M$ accepts $v_0$ we show that $v_1 = q_0v_0, v_i^+ = v_{i+1}$ for $1 \leq i < k$, and $v_k = q_f$. Consider a fixed $i$, $1 \leq i \leq k$. Recall that the $j$th constant in the sequence $\overline{c}$ is $c_{i_1b_j}$ and it occurs only at position $j$ in $\overline{c}$ (since there are no two identical constants in $\overline{c}$). Thus, given that

$$\langle v_i, v_i^+ \rangle = f_w(c_{i_1b_1}, f_w(c_{i_2b_2}, \ldots, f_w(c_{i_nb_n}, c_w) \cdots)),$$  

it follows from (13) that

$$s_i = f_w(z_{j_1}, f_w(z_{j_2}, \ldots, f_w(z_{j_{n'}}, s'_i) \cdots)),$$  

where $s'_i \in \{c_w, z_{m-2}, z_{m-1}, z_{m-1}, \ldots, z_{m-1}\}$, and $1 \leq j_{n'} \leq m$ for $1 \leq n' \leq n$. Recall that, for $j \leq m$, the $j$th constant in $\overline{t}_{sp}$ is $a_j$ and the $j$th constant in $\overline{r}_{sp}$ is $b_j$. Hence, for $1 \leq i \leq k$,

$$s_i[\overline{t}_{sp}] \in \{v_i, v_i^+, v_i^+b, v_i^+b^2\},$$  

$$s_i[\overline{r}_{sp}] \in \{v_i^+, v_i^+b, v_i^+b^2\}.$$  

Now, (10) implies that $v_1 = q_0v_0$. (11) implies that $a_i^+ = a_{i+1}$ for $1 \leq i < k$, and (12) implies that $a_k = q_f$. Thus $M$ accepts $v_0$.  

18
Assume that $M$ accepts $v_0$. We construct a substitution $\theta$ that solves $S^M_{wv}(F, G)$. Consider a valid computation of $M$ with input $v_0:
(v_1, v_2, v_3, \ldots, v_{k-1}, v_k, v_{k+1}),$
for some $k \geq 1$, i.e., $v_1 = q_0 v_0$, $v_i^+ = v_{i+1}$ for $1 \leq i \leq k$, and $v_{k+1} = \epsilon$ ($v_k = q_F$). We construct $F \theta$ like above, where the $s_i$'s are the following terms. Let $i$, $1 \leq i \leq k$, be fixed and assume that
\[
(v_i, v_i^+) = c_{a_{j_1} b_{j_1}} c_{a_{j_2} b_{j_2}} \cdots c_{a_{j_n} b_{j_n}},
\]
where $1 \leq j_n' \leq m$ for $1 \leq n' \leq n$. Let
\[
s_i = f_w(z_{j_1}, f_w(z_{j_2}, \ldots, f_w(z_{j_n}, s_i'))),
\]
where $s_i'$ is one of $c_w, z_{m_1-2}, z_{m_1-1}$ or $z_{m_1}$ (specified below). Given such $s_i$ for $1 \leq i \leq k$, obviously
\[
s_i[c_w, c_w, c_w] = "(v_i, v_{i+1})", \quad (1 \leq i \leq k).
\]
Hence, $F \theta[c_w, c_w, c_w] \in R_{mov}$ is a move-train. It follows from Lemma 5 that
\[
F \theta[c_w, c_w, c_w] \xrightarrow{\sigma} R_{mov} c_t,
\]
and then from Lemma 2(ii)$\Rightarrow$(i) that (for some term $G \theta$) $\theta$ solves $S^M_{mov}(F, G)$.

Next, we choose the $s_i'$'s, for $1 \leq i \leq k$, in $\{c_w, z_{m_1-2}, z_{m_1-1}, z_{m_1}\}$, so that the conditions (10–12) hold. Consider $\langle v_i, v_{i+1} \rangle$ above, let us call $a_{j_1} a_{j_2} \cdots a_{j_n}$ its first projection, denoted by $\pi_1(\langle v_i, v_{i+1} \rangle)$, and $b_{j_1} b_{j_2} \cdots b_{j_n}$ its second projection, denoted by $\pi_2(\langle v_i, v_{i+1} \rangle)$. It is easy to check that for a given choice of $s_i'$, the terms $s_i[\overline{r}_{sp}]$ and $s_i[\overline{r}_{sp}]$ are as follows:

<table>
<thead>
<tr>
<th>$s_i'$</th>
<th>$s_i[\overline{r}_{sp}]$</th>
<th>$s_i[\overline{r}_{sp}]$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$c_w$</td>
<td>$\pi_1(\langle v_i, v_{i+1} \rangle)$</td>
<td>$\pi_2(\langle v_i, v_{i+1} \rangle)$</td>
</tr>
<tr>
<td>$z_{m_1-2}$</td>
<td>$\pi_1(\langle v_i, v_{i+1} \rangle)[b^n]$</td>
<td>$\pi_2(\langle v_i, v_{i+1} \rangle)[b^n]$</td>
</tr>
<tr>
<td>$z_{m_1-1}$</td>
<td>$\pi_1(\langle v_i, v_{i+1} \rangle)[b^n]$</td>
<td>$\pi_2(\langle v_i, v_{i+1} \rangle)[b^n]$</td>
</tr>
<tr>
<td>$z_{m_1}$</td>
<td>$\pi_1(\langle v_i, v_{i+1} \rangle)[b^n]$</td>
<td>$\pi_2(\langle v_i, v_{i+1} \rangle)[b^n]$</td>
</tr>
</tbody>
</table>

Now, the key point to observe is that, for $1 \leq i \leq k$, if $\pi_2(\langle v_{i-1}, v_i \rangle)$ and $\pi_1(\langle v_i, v_{i+1} \rangle)$ are distinct, the one of them is $v_i$ and the other one is $v_i \overline{b}$. Hence, the table shows that it is possible to define the $s_i$'s so that $s_i[\overline{r}_{sp}] = s_{i+1}[\overline{r}_{sp}]$ for $1 \leq i < k$ and $s_k[\overline{r}_{sp}] = "\overline{b}"$. It is also necessary to assume that $\pi_1(\langle v_1, v_2 \rangle) = v_1$, and to define $s_1$ so that $s_1[\overline{r}_{sp}] = "q_0 v_0"$. The conditions (10–12) follow. Hence, $\theta$ solves $S^M_{sp}("q_0 v_0", F)$ by Lemma 1(ii)$\Rightarrow$(i).
Let us consider a fixed universal Turing machine $M_u$ with input alphabet $\Sigma_u$ and initial state $q_0$. Any pair $(M, v)$, where $M$ is a TM and $v$ an input string for $M$ is encoded effectively as a string over $\Sigma_u$, denoted by $(M, v)$. The details of such an encoding are not relevant here and can be found for example in Hopcroft and Ullman [20]. The universal TM accepts $(M, v)$ if and only if $M$ accepts $v$. The following corollary is an easy consequence of Theorem 6. Recall that a simple second-order equation is one where all occurrences of second-order variables have ground arguments.

**Corollary 1** There is a simple second-order equation $S^u(x, F, G)$ of depth 4 and of the form

$$g(F(\bar{t}_1), G(\bar{t}_2)) \approx g(f(x, F(\bar{t}_3)), g(F(\bar{t}_4), G(\bar{t}_5))),$$

such that the problem of determining whether $S^u(t, F, G)$ is solvable for a given ground term $t$, is undecidable.

**Proof.** Consider the system

$$S^{M_u}(x, F, G) = \{ F(\bar{t}_1) \approx f(x, F(\bar{t}_3)), G(\bar{t}_2) \approx g(F(\bar{t}_4), G(\bar{t}_5)) \},$$

for some sequences $\bar{t}_i$, $1 \leq i \leq 5$, of ground terms. Pair the two equations together to form $S^u(x, F, G)$. The depth of $S^u(x, F, G)$ is 4 since the elements of each $\bar{t}_i$ have depth $\leq 1$. Evidently, for any given term $t$, $S^u(t, F, G)$ is solvable if and only if $S^{M_u}(t, F, G)$ is solvable. In particular, given a TM $M$ and input $v$ for $M$, $S^u("q_0(M, v)", F, G)$ is solvable if and only if $S^{M_u}_{(M, v)}(F, G)$ is solvable if and only if (by Theorem 6) $M_u$ accepts $(M, v)$ if and only if $M$ accepts $v$.

Let us call the second-order equation $S^u$ in Corollary 1 a universal second-order equation and let us denote the language of $S^u$ by $L_u$.

**Corollary 2** Second-order unification is undecidable under the following restrictions:

1. there are no first-order variables,
2. at most two variables,
3. at most five occurrences of variables,
4. the equations are simple (Schubert [28]), and
5. the arguments of all variables have constantly bounded depth.
In the following section we get further improvements of this result by applying certain encoding techniques in Farmer [13].

It is interesting to note that, by applying the reduction in Degtyarev and Voronkov [10] to a system of simple second-order equations, one obtains a system of rigid equations with ground left-hand sides.\(^5\) (The converse does not hold, i.e., the reduction from a system of rigid equations with ground left-hand sides, by using Theorem 2, does in general not yield a system of simple second-order equations.) Thus, by using Schubert’s result that is confirmed by Corollary 2, one obtains an elegant proof of the following statement.

**Corollary 3 (Plaisted [26])** *SREU is undecidable with ground left-hand sides.*

### 6 A complement to Farmer’s theorem

Let us recall the following result.

**Theorem 7 (Farmer [13])** *There is an integer \(n\) such that the second-order unification problem is undecidable for all nonmonadic languages, that contain at least \(n\) second-order variables.*

One important point of this result is that all the second-order variables may be unary. So undecidability of second-order unification arises for all non-monadic languages with sufficiently many second-order variables, even if all of them are unary and there are no first-order variables and only one constant in the language. However, as is noted in Farmer [13, page 30], *there is a possibility, that there is some second-order, nonmonadic language containing a small number of second-order variables for which second-order unification is decidable.*

The main result of this section is Theorem 8, showing that this is not possible if the arities of the second-order variables are large enough, in which case the undecidability arises already with two second-order variables. The above possibility remains only if there is one second-order variable, or if there is a small number of second-order variables with low arities.

We use a special case of a result in Farmer [13, Lemma 6.5] (Lemma 7) to show that Corollary 2 holds for all nonmonadic languages. We make explicit some additional information that we extract from the main part of its proof.\(^6\)

\(^5\)This observation was made by Voronkov.

\(^6\)Lemma 7 holds actually not just for simple equations but for a larger class of second-order equations that are called “rigid” by Farmer. This notion is not related to the definition of rigid equations in the context of rigid \(E\)-unification.
Lemma 7 Let $L_1$ be a nonmonadic second-order language and let $L$ be the language \((\{f, c\}, \mathcal{X}_L, \mathcal{F}_L)\), where $f$ is a binary function symbol and $c$ is a constant. There is an effective mapping $\varphi : \mathcal{T}_{L_1} \to \mathcal{T}_L$ such that, for all simple $e = s \approx t$ in $L_1$:

1. $\varphi(e) = \varphi(s) \approx \varphi(t)$ in $L$ is simple,
2. $e$ is solvable in $L_1$ if and only if $\varphi(e)$ is solvable in $L$,
3. the set of variables in $e$ coincides with the set of variables in $\varphi(e)$,
4. the number of variable occurrences in $e$ and $\varphi(e)$ are equal,
5. if $s = s_1\{x \mapsto s_2\}$ for some simple $s_1$ and ground $s_2$ then $\varphi(s) = \varphi(s_1)\{x \mapsto \varphi(s_2)\}$.

Theorem 8 There is a positive integer $n$, such that, for any nonmonadic second-order language $L$ with at least two second-order variables with arity $\geq n$, the unification problem for $L$ is undecidable already for simple equations with at most five variable occurrences having arguments of depth $\leq n$.

Proof. It is enough to prove the statement for some second-order variables $F$ and $G$ and $L = (\{f, c\}, \emptyset, \{F, G\})$, where $f$ is a binary function symbol, and $c$ is a constant (cf [13, Lemma 2.1]). Let $L'$ be $L$ expanded with the first-order variable $x$. Consider the universal second-order equation $S^n(x, F, G)$ (that is obviously simple) and let $\varphi : \mathcal{T}_{L_{n}} \to \mathcal{T}_L$ be given by Lemma 7. Let $S'(x, F, G) = \varphi(S^n(x, F, G))$. It follows that for any term $t \in \mathcal{T}_{L_{n}}$, $S^n(t, F, G)$ is solvable in $L_{n}$ if and only if $\varphi(S^n(t, F, G))$ is solvable in $L'$ (i.e., in $L$) if and only if $S'(\varphi(t), F, G)$ is solvable in $L$. The statement follows now from Corollary 1 for $n$ equal to some integer greater that the arities of $F$ and $G$ and the depth of $S'(x, F, G)$.

7 Some open problems

Despite the similarity of SREU and second-order unification in general, their monadic fragments (i.e., when all function symbols have arity $\leq 1$) seem to be farther apart. The reason is that the decidability of monadic second-order unification can be proved by reduction to word equations [12], whereas monadic SREU is only known to reduce to a nontrivial extension of word equations [19] and its decidability is currently an open problem, with only some special decidable cases [19, 6]. It is also known that SREU is undecidable with three rigid equations [18] and decidable with one rigid equation [14].
The two rigid equations case remains an intriguing open problem, and the relationship to second-order unification might be useful to settle this question. Further open problems related to SREU are discussed in Voronkov [34]. With respect to the number of variables, the decidability of SREU has recently been settled completely [4, 31].

We conjecture that, by applying the techniques that are used by Farmer (in particular [13, Lemma 5.2 and Lemma 6.1]), to the universal second-order equation $S^n$, one can obtain a more elementary proof of Farmer’s main theorem that holds already for simple equations. We estimate that the number of unary second-order variables that the reduction from $S^n$ would lead to is roughly $4n$ where $n$ is the maximum of the arities of the second-order variables in $S^n$. It is still not known whether second-order unification is decidable for “small” number of second-order variables with “low” arities. As we have shown, when the arities can be large enough, then undecidability arises already with two second-order variables. It is also an open problem if second-order unification is decidable with one second-order variable, unless there are at most two occurrences of the second-order variable [22].
