Background & research questions

- Opaque Grapheme-to-Phoneme Correspondence (GPC) in logographic languages, e.g. Mandarin Chinese.
- Little is known whether both phonological and orthographic forms are activated during word production.
- Are orthographic representations activated in speaking and phonological representations activated in writing?
- i.e. is there any modality specific effect?

Experiment procedure

Primes: orthography relatedness O+ VS O-
Blocks: phonological blocking phono+ VS control
semantic blocking seman+ VS control

Language production

• Conceptualization
• Word meaning
• Word sound
• Word form

Paradigm: masked-primed cyclic picture naming
Participants: native Mandarin Chinese speakers
Task:
Group A - naming aloud Group B - writing
Measurement: Reaction times (RTs)

Results

For speaking (N=16) & writing (N15) tasks, RTs shorter in phonological blocks than control (phonological facilitation effect);
RTs in semantic blockings longer than control (semantic interference effect);
RTs in O+ trials are shorter than O- trials, showing that related orthography primes facilitate picture naming.

Conclusion

- Both orthographic and phonological representations are activated during speaking and writing.
