Measurement of CP violation parameters in $B^0 \to D K^{\ast 0}$ decays

The LHCb collaboration

Abstract
An analysis of $B^0 \to D K^{\ast 0}$ decays is presented, where $D$ represents an admixture of $D^0$ and $\bar{D}^0$ mesons reconstructed in four separate final states: $K^- \pi^+$, $\pi^- K^+$, $K^+ K^-$ and $\pi^+ \pi^-$. The data sample corresponds to 3.0 fb$^{-1}$ of proton-proton collision, collected by the LHCb experiment. Measurements of several observables are performed, including CP asymmetries. The most precise determination is presented of $r_B(D K^{\ast 0})$, the magnitude of the ratio of the amplitudes of the decay $B^0 \to D K^+ \pi^-$ with a $b \to u$ or a $b \to c$ transition, in a $K\pi$ mass region of $\pm 50$ MeV/c$^2$ around the $K^{\ast}(892)$ mass and for an absolute value of the cosine of the $K^{\ast 0}$ helicity angle larger than 0.4.

1 Introduction

Direct \( CP \) violation can arise in \( B^0 \to DK^{*0} \) decays from the interference between the two colour-suppressed \( b \to u \) and \( b \to c \) transitions shown in the Feynman diagrams of Fig. 1 when the \( D^0 \) and \( \bar{D}^0 \) mesons decay to a common final state. Here and in the following, \( D \) represents a neutral meson that is an admixture of \( D^0 \) and \( \bar{D}^0 \) mesons and \( K^{*0} \) represents the \( K^{*}(892)^0 \) meson. Inclusion of charge conjugate processes is implied unless specified otherwise.

The amount of \( CP \) violation is related to the value of the weak phase

\[
\gamma \equiv \arg \left( -\frac{V_{ud}V_{ub}^*}{V_{cd}V_{cb}^*} \right),
\]

the least-well determined angle of the unitarity triangle, where \( V_{ij} \) are elements of the Cabibbo-Kobayashi-Maskawa (CKM) matrix \[1\]. The current experimental measurements are \( \gamma = (72.0^{+14.7}_{-15.6})^\circ \) by the LHCb collaboration \[2\], \( \gamma = (69^{+17}_{-16})^\circ \) by the BaBar \[3\] collaboration and \( \gamma = (68^{+15}_{-14})^\circ \) by the Belle collaboration \[4\]. This angle can be measured with extremely small theoretical uncertainties \[5\], using decay modes proceeding through amplitudes involving only the exchange of a \( W \) boson. Such methods to determine \( \gamma \) from hadronic \( B \)-decay rates were originally proposed in Refs. \[6,7\] for \( B \to DK \) decays and can be applied to the \( B^0 \to DK^{*0} \) decay \[8\]. In this decay, the charge of the kaon from the \( K^{*0} \to K^+\pi^- \) decay unambiguously identifies the flavour of the decaying \( B \) meson. Hence, no flavour tagging is needed.

The use of these specific neutral \( B \) meson decays is interesting since the interfering amplitudes are of comparable size, as opposed to the charged \( B^+ \to DK^+ \) decay that involves both colour-suppressed and colour-allowed amplitudes; hence the system could exhibit larger \( CP \)-violating effects. Contributions from \( B^0 \) decays to the \( DK^+\pi^- \) final state through non-\( K^{*0} \) intermediate resonances can pollute the \( DK^{*0} \) reconstructed signal candidates because of the large natural width of the \( K^{*0} \). They are treated following Ref. \[9\], with the use of a coherence factor, \( \kappa \), in addition to the hadronic parameters \( r_B \) and \( \delta_B \), defined as

![Feynman diagrams](image-url)
where $A_{ub}(p)$ and $A_{cb}(p)$ are the amplitudes of the $b \to u$ and $b \to c$ transitions, respectively, to the $B^0 \to DK^+\pi^-$ decays, $\delta(p)$ is the strong-phase difference between the two amplitudes and $p$ is a point in the three-body phase space of the $B^0$ meson. The integrals are defined over the phase space considered here, namely in a $K^+\pi^-$ mass range of $\pm 50 \text{ MeV}/c^2$ around the nominal $K^{*0}$ mass [10] and for an absolute value of the cosine of the helicity angle $\theta^*$ greater than 0.4, where $\theta^*$ is defined as the angle between the $K$ momentum and the opposite of the $B$ momentum in the $K^{*0}$ rest frame. The formalism of (2)-(4) applies to the generic three-body decay $B^0 \to DK^+\pi^-$ with any number of intermediate resonances included. The integration range is restricted here to the $K^{*0}$ resonance in order to obtain a large value of the coherence factor.

This paper presents two measurements of the ratio, $R_{CP+}$, of flavour-averaged partial widths of the $B^0 \to DK^{*0}$ decay with the $D$ decaying to a $CP$-even eigenstate,

$$R_{CP+} \equiv 2 \times \frac{\Gamma(B^0 \to D_{CP+}K^{*0}) + \Gamma(B^0 \to D_{CP+}K^{*0})}{\Gamma(B^0 \to D^0 K^{*0}) + \Gamma(B^0 \to D^0 K^{*0})}. \quad (5)$$

The relation above is approximated using specific final states of the $D$ meson as $R_{CP+} \approx R_{d}^{hh}$, neglecting corrections from doubly Cabibbo-suppressed $D^0 \to K^+\pi^-$ decays, with

$$R_{d}^{hh} \equiv \frac{\Gamma(B^0 \to D(h^+h^-)K^{*0}) + \Gamma(B^0 \to D(h^+h^-)K^{*0})}{\Gamma(B^0 \to D(K^-\pi^+)K^{*0}) + \Gamma(B^0 \to D(K^{+}\pi^-)K^{*0})} \times \frac{B(D^0 \to K^+\pi^-)}{B(D^0 \to h^+h^-)}. \quad (6)$$

where $h$ represents either a $\pi$ or a $K$ meson. This quantity is related to the $\gamma$ angle and the hadronic parameters by [11]

$$R_{d}^{hh} = \frac{1 + r_D^2 + 2r_D K \cos \delta_B \cos \gamma}{1 + r_D^2 + 2r_D K \cos (\delta_B - \delta_D) \cos \gamma}, \quad (7)$$

where $r_D$ and $\delta_D$ are the magnitude of the ratio and the phase difference, respectively, between the amplitudes of the $D^0 \to K^+\pi^-$ and $D^0 \to K^-\pi^+$ decays. Charm mixing and $CP$ violation in the decays of $D$ mesons have an effect on the determination of $\gamma$ [7,12] but are neglected here because of the large expected value of $r_B$. 

2
Measurements of the $B^0$-$\overline{B}^0$ partial decay-rate asymmetry, $A_{d}^{h\bar{h}}$, using $D \rightarrow h^+h^-$ final states are also presented,

\[
A_{d}^{h\bar{h}} = \frac{\Gamma(\overline{B}^0 \rightarrow D(h^+h^-)\overline{K}^{*0}) - \Gamma(B^0 \rightarrow D(h^+h^-)K^{*0})}{\Gamma(\overline{B}^0 \rightarrow D(h^+h^-)\overline{K}^{*0}) + \Gamma(B^0 \rightarrow D(h^+h^-)K^{*0})} = \frac{2r_B \kappa \sin \delta_B \sin \gamma}{1 + r_B^2 + 2r_B \kappa \cos \delta_B \cos \gamma}. \tag{8}
\]

The $\overline{B}^0$-$B^0$ asymmetry, $A_{d}^{K}\pi$, obtained from the Cabibbo-favoured decay $B^0 \rightarrow DK^{*0}$ with $D \rightarrow K^+\pi^-$, where the two kaons from the $D$ and the $K^{*0}$ decay have the same sign, is

\[
A_{d}^{K}\pi = \frac{\Gamma(\overline{B}^0 \rightarrow D(K^-\pi^+)\overline{K}^{*0}) - \Gamma(B^0 \rightarrow D(K^+\pi^-)K^{*0})}{\Gamma(\overline{B}^0 \rightarrow D(K^-\pi^+)\overline{K}^{*0}) + \Gamma(B^0 \rightarrow D(K^+\pi^-)K^{*0})} = \frac{2r_B r_D \kappa \sin(\delta_B - \delta_D) \sin \gamma}{1 + r_B^2 r_D^2 + 2r_B r_D r_D \kappa \cos(\delta_B - \delta_D) \cos \gamma}. \tag{9}
\]

The Cabibbo-suppressed decay $B^0 \rightarrow DK^{*0}$ with $D \rightarrow \pi^+K^-$, where the two kaons have opposite charge, is studied for the first time by LHCb. The ratios of suppressed $B^0 \rightarrow D(\pi^+K^-)K^{*0}$ tofavoured $B^0 \rightarrow D(K^+\pi^-)K^{*0}$ partial widths are measured separately for $B^0$ and $\overline{B}^0$, and defined as $R_d^+$ and $R_d^-$, respectively,

\[
R_d^+ = \frac{\Gamma(B^0 \rightarrow D(\pi^+K^-)K^{*0})}{\Gamma(B^0 \rightarrow D(K^+\pi^-)K^{*0})} = \frac{r_B^2 + r_D^2 + 2r_B r_D \kappa \cos(\delta_B + \delta_D + \gamma)}{1 + r_B^2 r_D^2 + 2r_B r_D r_D \kappa \cos(\delta_B - \delta_D + \gamma)}, \tag{10}
\]

\[
R_d^- = \frac{\Gamma(\overline{B}^0 \rightarrow D(\pi^-K^+)\overline{K}^{*0})}{\Gamma(\overline{B}^0 \rightarrow D(K^-\pi^+)\overline{K}^{*0})} = \frac{r_B^2 + r_D^2 + 2r_B r_D \kappa \cos(\delta_B + \delta_D - \gamma)}{1 + r_B^2 r_D^2 + 2r_B r_D r_D \kappa \cos(\delta_B - \delta_D - \gamma)}. \tag{11}
\]

In $pp$ collisions, $B_s^0$ mesons are produced and can decay to the same final state, $B_s^0 \rightarrow D\overline{K}^{*0}$ [13]. Similar asymmetry observables to those defined above for $B^0$ mesons are measured with $B_s^0$ mesons. These are the $\overline{B}_s^0$-$B_s^0$ asymmetry, $A_{s}^{h\bar{h}}$, obtained from the $K^+K^−$ and $\pi^+\pi^−$ final states of the $D$ meson,

\[
A_{s}^{h\bar{h}} = \frac{\Gamma(\overline{B}_s^0 \rightarrow D(h^+h^-)\overline{K}^{*0}) - \Gamma(B_s^0 \rightarrow D(h^+h^-)K^{*0})}{\Gamma(\overline{B}_s^0 \rightarrow D(h^+h^-)\overline{K}^{*0}) + \Gamma(B_s^0 \rightarrow D(h^+h^-)K^{*0})}, \tag{12}
\]

and the asymmetry, $A_{s}^{K}\pi$, from the Cabibbo-favoured decay $B_s^0 \rightarrow D(\pi^-K^+)\overline{K}^{*0}$, where the two kaons have opposite charge,

\[
A_{s}^{K}\pi = \frac{\Gamma(\overline{B}_s^0 \rightarrow D(\pi^+K^-)\overline{K}^{*0}) - \Gamma(B_s^0 \rightarrow D(\pi^-K^+)\overline{K}^{*0})}{\Gamma(\overline{B}_s^0 \rightarrow D(\pi^+K^-)\overline{K}^{*0}) + \Gamma(B_s^0 \rightarrow D(\pi^-K^+)\overline{K}^{*0})}. \tag{13}
\]

The $B_s^0 \rightarrow D(K^-\pi^+)\overline{K}^{*0}$ decay, where the two kaons have the same charge, is highly suppressed and therefore unobserved with the current data sample. Finally, the ratios of the flavour-averaged partial widths of the $B^0$ and $B_s^0$ decays, when the $D$ meson is reconstructed as $D \rightarrow h^+h^-$, $R_{ds}^{h\bar{h}}$, are also considered,

\[
R_{ds}^{h\bar{h}} = \frac{\Gamma(\overline{B}_s^0 \rightarrow D(h^+h^-)\overline{K}^{*0}) + \Gamma(B_s^0 \rightarrow D(h^+h^-)K^{*0})}{\Gamma(\overline{B}_s^0 \rightarrow D(h^+h^-)\overline{K}^{*0}) + \Gamma(B_s^0 \rightarrow D(h^+h^-)K^{*0})}. \tag{14}
\]
The observables related to $B^0_s$ decays could in principle also be used to determine the value of $\gamma$. However, the observables pertaining to $B^0$ mesons are far more sensitive, owing to the fact that the ratio of interfering amplitudes is closer to unity. Those related to $B^0_s$ mesons are measured and reported in this paper but are not yet precise enough to provide any constraint on $\gamma$.

2 The LHCb detector, data set and event selection

The study reported here is based on a data sample of $pp$ collisions obtained from 3.0 fb$^{-1}$ of integrated luminosity with the LHCb detector [14]. The centre-of-mass energy was 7 TeV during the year 2011, when approximately $1/3$ of the data were collected, and 8 TeV during the year 2012.

The LHCb detector [14] is a single-arm forward spectrometer covering the pseudorapidity range $2 < \eta < 5$, designed for the study of particles containing $b$ or $c$ quarks. The detector includes a high-precision tracking system consisting of a silicon-strip vertex detector surrounding the $pp$ interaction region [15], a large-area silicon-strip detector located upstream of a dipole magnet with a bending power of about 4 Tm, and three stations of silicon-strip detectors and straw drift tubes placed downstream of the magnet. The tracking system provides a measurement of momentum, $p$, with a relative uncertainty that varies from 0.4% at low momentum to 0.6% at 100 GeV/$c$. The minimum distance of a track to a primary vertex, the impact parameter, is measured with a resolution of $(15 + 29/p_T) \mu m$, where $p_T$ is the component of $p$ transverse to the beam, in GeV/$c$. Different types of charged hadrons are distinguished using information from two ring-imaging Cherenkov detectors [16]. Photon, electron and hadron candidates are identified by a calorimeter system consisting of scintillating-pad and preshower detectors, an electromagnetic calorimeter and a hadronic calorimeter. Muons are identified by a system composed of alternating layers of iron and multiwire proportional chambers. The trigger [17] consists of a hardware stage, based on information from the calorimeter and muon systems, followed by a software stage, which applies a full event reconstruction.

The analysis uses events triggered at the hardware level either when one of the charged tracks of the signal decay gives a large enough energy deposit in the calorimeter system (hadron trigger), or when one of the particles in the event, not reconstructed as forming the signal candidate, fulfills any trigger requirement (i.e. mainly events triggered by one high $p_T$ muon, hadron, photon or electron coming from the decay of the other $B$ meson in the event). The software trigger requires a two-, three- or four-track secondary vertex with a large sum of the $p_T$ of the charged particles and a significant displacement from the primary $pp$ interaction vertices (PVs). At least one charged particle should have $p_T > 1.7$ GeV/$c$ and $\chi^2_{IP}$ with respect to any PV greater than 16, where $\chi^2_{IP}$ is defined as the difference in $\chi^2$ of a given PV reconstructed with and without the considered particle. A multivariate algorithm [18] is used for the identification of secondary vertices consistent with the decay of a $b$ hadron.

Approximately 1 million simulated events are used to describe the signal shapes and
to compute the efficiencies when data-driven methods are not available. In the simulation, 
\( pp \) collisions are generated using \( \text{PYTHIA} \) \cite{20,21} with a specific LHCb configuration \cite{21}. Decays of hadronic particles are described by \( \text{EVGEN} \) \cite{22}, in which final state radiation is generated using \( \text{PHOTOS} \) \cite{23}. The interaction of the generated particles with the detector and its response are implemented using the \( \text{GEANT4} \) toolkit \cite{24} as described in Ref. \cite{25}.

Candidate \( B^0 \rightarrow D K^0 \) decays are reconstructed in events fulfilling these trigger conditions combining \( D \) mesons reconstructed in the \( K^\pm \pi^\mp, K^+K^- \) and \( \pi^+\pi^- \) decays and \( K^*0 \) mesons reconstructed in the \( K^+\pi^- \) final state. The invariant masses of the \( D \) and \( K^*0 \) mesons are required to be within 20 MeV/c\(^2\) and 50 MeV/c\(^2\) of their known masses \cite{10}, respectively. The \( B \) candidate momentum is refit constraining the mass of the \( D \) meson to its known value. It is required that \( |\cos \theta^*| > 0.4 \).

A boosted decision tree (BDT) \cite{26} is used with the algorithm described in Ref. \cite{27} to separate signal from combinatorial background. Separate BDTs are optimised for \( K^\pm\pi^\mp, K^+K^- \) and \( \pi^+\pi^- \) final states of the \( D \) meson. In all cases the samples used to train the BDT are fully simulated events for the signal and candidates from the upper sideband of the \( B \) mass distribution in data for the background. This upper sideband is defined as events with a \( DK^0 \) invariant mass between 5.8 GeV/c\(^2\) and 7 GeV/c\(^2\), lying outside the region used for the fit described in Sect. \cite{3}. The variables used by the BDT to differentiate signal and background are: the \( p_T \) of each particle in the final state; the fit quality of the \( D \) and \( B^0 \) vertices; the \( K^*0, D \) and \( B^0 \) \( \chi^2_{IP} \); the angle between the \( B^0 \) momentum and the vector from the PV to the \( B^0 \) decay vertex; the significance of the displacement of the four final-state tracks from the PV.

Thresholds on the BDT classifier are optimised with respect to the signal significance of the \( B^0 \) decay modes for the three final states \( B^0 \rightarrow D(\pi^+K^-)K^0, B^0 \rightarrow D(K^+K^-)K^0 \) and \( B^0 \rightarrow D(\pi^+\pi^-)K^*0 \), where the significance is defined as \( S/\sqrt{S+B} \) with \( S \) and \( B \) the expected number of signal and background candidates. The efficiencies of the selection based on the BDT output classifier are equal to 69\%, 71\% and 75\% for the \( D \rightarrow K^\pm\pi^\mp, D \rightarrow K^+K^- \) and \( D \rightarrow \pi^+\pi^- \) decay channels, respectively.

To improve the purity of the data sample, further selection requirements are made in addition to the BDT. Particle identification (PID) criteria are applied and only well identified pions and kaons are retained. The kaon identification efficiency of the PID criteria is equal to 87\% with a pion misidentification rate of 5\%. Possible contamination from \( A_0^0 \rightarrow D^0\pi^-h^- \) decays is reduced by keeping only kaon candidates incompatible with being a proton.

A potentially significant background is due to events where the \( K \) from \( D \rightarrow K^\pm\pi^\mp \) decays is misidentified as a \( \pi \) and the \( \pi \) is simultaneously mis-identified as a \( K \). This causes cross-feed from the favoured \( B^0 \rightarrow D(K^+\pi^-)K^0 \) decay into the suppressed \( B^0 \rightarrow D(\pi^+K^-)K^0 \) decay. A veto is applied on the \( D \) invariant mass computed with a pion mass assignment for the kaon and a kaon mass assignment for the pion. Only candidates for which this invariant mass differs by more than 7 MeV/c\(^2\) from the known \( D^0 \) mass \cite{10} are kept, reducing this background to a negligible level while keeping 97\% of the signal candidates.

Another potential background is due to charmless decays \( B^0 \rightarrow h^+h'^-K^+\pi^- \), where \( h'\)
is also $\pi$ or $K$. It is removed by requiring the $D$ flight distance with respect to the $B$ vertex to exceed three times its uncertainty. Specific peaking backgrounds from $B^0(s) \to D^+_s h^+$ decays are eliminated by applying a veto on candidates for which the invariant mass of three of the four charged mesons is compatible within $\pm 15\text{ MeV}/c^2$ of the known $D^+$ or $D^+_s$ masses.

After all selections are applied, $0.9\%$ of the events contain more than one signal candidate. Only the candidate with the largest $B$ flight distance with respect to the PV, divided by its uncertainty, is retained. In case several PVs are reconstructed, the PV with respect to which the $B$ candidate has the smallest displacement is used.

Figure 2 shows the background-subtracted $K^+\pi^-$ invariant mass of the $K^{*0}$ candidates used to reconstruct $B^0 \to DK^{*0}$ decays, obtained with the $s$Plot technique. All selections described above have been applied except the requirement on the $K^{*0}$ candidate mass. This distribution is fitted with a relativistic Breit-Wigner function to describe the $K^{*0}$ signal and a first-order polynomial for the non-$K^{*0}$ contribution. From the fit result, it is estimated that $(8.4 \pm 3.4)\%$ of the signal $B^0$ candidates are formed with a $K^+\pi^-$ pair that does not originate from a $K^{*0}$ decay, in the $K^+\pi^-$ mass region considered for the analysis.

### 3 Invariant mass fit

The numbers of reconstructed signal $B^0$ and $B^0_s$ candidates are determined from an unbinned maximum-likelihood fit to the $DK^{*0}$ invariant mass distributions. Candidates are split into eight categories, which are fitted simultaneously: $D(K^+\pi^-)K^{*0}$, $D(K^-\pi^+)\bar{K}^{*0}$, $D(\pi^-K^+)K^{*0}$, $D(\pi^-K^-)\bar{K}^{*0}$, $D(K^+K^-)K^{*0}$, $D(K^+K^-)\bar{K}^{*0}$, $D(\pi^+\pi^-)\bar{K}^{*0}$ and $D(\pi^+\pi^-)K^{*0}$ candidates. The mass distribution of
each category is fitted with a sum of probability density functions (PDFs) modelling the various contributing components:

1. The $B^0$ and $B^0_s$ signals are both described by a sum of two Gaussian functions with a common mean;

2. The combinatorial background is described by an exponential function;

3. The cross-feed from $B^0 \to D \rho^0$ decays, where one $\pi$ from the $\rho^0 \to \pi^+ \pi^-$ decay is misidentified as a $K$, is described by a non-parametric PDF determined from simulation; the coefficients of the two functions in the linear combinations are different for the branching fractions from Ref. [10] and the corresponding efficiencies from simulation. The $D^*$ for a defined helicity eigenstate, where the weights take into account the relative numbers of cross-feed events in the $D^*$ category using the relative efficiencies from Ref. [10] and selection efficiencies from simulation. As a negligible CP asymmetry is expected for the $B^0 \to D (K^+ \pi^-) \rho^0$ background, the numbers of cross-feed events in the $D K^{*0}$ categories are constrained to be identical to those of the corresponding $DK^{*0}$ categories.

   A separate fit to $B^0 \to D (K^+ \pi^-) \rho^0$ candidates in the same data sample is performed, reconstructing $\rho^0$ in the $\pi^+ \pi^-$ final state within a $\pm 50 \text{MeV}/c^2$ mass range around the known $\rho^0$ mass. The observed number of $B^0 \to D (K^+ \pi^-) \rho^0$ candidates is used, along with the efficiency to reconstruct $B^0 \to D (K^+ \pi^-) \rho^0$ candidates as $B^0 \to D (K^+ \pi^-) K^{*0}$ from simulation, to constrain the number of cross-feed events in the $D (K^+ \pi^-) K^{*0}$ category. The numbers of cross-feed candidates in the other categories are derived from the $D (K^+ \pi^-) K^{*0}$ category using the relative $D$ branching fractions from Ref. [10] and selection efficiencies from simulation. The partially reconstructed background accumulates at masses lower than the known $B^0$ mass. Its shape depends on the unknown fraction of longitudinal polarisation in the $B^0 \to D^* K^{*0}$ and $\bar{B}^0_s \to D^* K^{*0}$ decays, i.e. the probability that the $D^*$ in these decays is produced with helicity equal to 0. In order to model the $\bar{B}^0_s \to D^* K^{*0}$ contribution, a PDF is built from a linear combination of two non-parametric functions corresponding to the three orthogonal helicity amplitudes. Two of the orthogonal helicity amplitudes result in the same distribution in invariant mass because of parity conservation in the $D^{*0} \gamma$ decay, hence simplifying the model. Each function, modelled from simulated events, corresponds to the weighted sum of the $D^{*0} \to D^{0} \gamma$ and $D^{*0} \to D^{0} \pi^0$ contributions for a defined helicity eigenstate, where the weights take into account the relative $D^{*0}$ decay branching fractions from Ref. [10] and the corresponding efficiencies from simulation. The $B^0 \to D^* K^{*0}$ background is modelled in a similar way, shifting the shape obtained for the $\bar{B}^0_s \to D^* K^{*0}$ decay by the known difference between the $B^0$ and $B^0_s$ masses [10]. The coefficients of the two functions in the linear combinations are different for the $B^0 \to D^* K^{*0}$ and $\bar{B}^0_s \to D^* K^{*0}$ decays but are common to the 8 categories and are free parameters in the fit.

The yields of the $B^0_s$ and $\bar{B}^0_s$ partially reconstructed backgrounds in the $D (K^+ \pi^-) K^{*0}$ categories are fixed to zero since the $\bar{B}^0_s \to D^* K^{*0}$ decay modes have negligible total
The signal yields determined from the invariant mass fit are corrected in order to evaluate which is different for each $D$ yields of the $B$. These corrections account for selection efficiencies obtained from simulation.

4 Systematic uncertainties

The signal yields determined from the invariant mass fit are corrected in order to evaluate the asymmetries and ratios described in [5]-[13]. These corrections account for selection
efficiency and detection asymmetry, \(B\)-\(\bar{B}\) production asymmetry and its dilution due to mixing, misidentification of \(D\) meson decays, \(D^0\) decay branching fractions, hadronisation fractions and biases introduced by the fit model. The uncertainties in these corrections cause systematic uncertainties in the results. Systematic uncertainties are also introduced by the uncertainties in the various constraints on the invariant mass model. The systematic uncertainties incurred from all sources are obtained combining in quadrature the individual uncertainties and are summarised in Table 2.

Figure 3: Distributions of (top left) \(D(\pi^-K^+)\bar{K}^{*0}\), (top right) \(D(\pi^+K^-)K^{*0}\), (bottom left) \(D(K^-\pi^+)\bar{K}^{*0}\) and (bottom right) \(D(K^+\pi^-)K^{*0}\) invariant mass. The data (black points) and the fitted invariant mass model (thick solid line) are shown. The PDFs corresponding to the different species are indicated in the legend: the \(B^0\) signal, the \(B^0_s\) signal, combinatorial background, \(B^0 \rightarrow D\rho^0\) background, partially reconstructed \(B^0_s \rightarrow D^*\bar{K}^{*0}\) and \(B^0 \rightarrow D^*K^{*0}\) backgrounds.
4.1 Efficiencies

Separate corrections are applied to account for differing trigger and PID efficiencies. These efficiencies are obtained from real data by means of low-background calibration samples of kaons and pions from $D^{*\pm} \rightarrow D(K^{\mp}\pi^{\pm})\pi^{\pm}$ decays \cite{30}. They are evaluated separately for $\bar{B}$ and $B$ modes to account for detection asymmetries. The relative trigger and PID efficiencies differ from unity by 1% and 5%, respectively, and their uncertainties result in the systematic uncertainties given in Table 2.

Another correction is applied to account for the differences in the kinematic selection requirements of the different decay modes. The efficiencies are evaluated from simulated data.

---

Figure 4: Distributions of (top left) $D(K^{+}K^{-})K^{*0}$, (top right) $D(K^{+}K^{-})K^{*0}$, (bottom left) $D(\pi^{+}\pi^{-})K^{*0}$ and (bottom right) $D(\pi^{+}\pi^{-})K^{*0}$ invariant mass. The data (black points) and the fitted invariant mass model (thick solid line) are shown. The PDFs corresponding to the different species are indicated in the legend: the $B^{0}$ signal, the $B_{s}^{0}$ signal, combinatorial background, $B^{0} \rightarrow D\rho^{0}$ background and partially reconstructed $B_{s}^{0} \rightarrow D^{*}K^{*0}$ and $B^{0} \rightarrow D^{*}K^{*0}$ backgrounds.
and they are assumed to be equal for the $B^0 \to D(K^+\pi^-)K^{*0}$ and $B^0 \to D(\pi^+K^-)K^{*0}$ decays. They differ between decay modes by 8\% at maximum. The uncertainties on these efficiencies affect the measured observables as shown in Table 2. It is noted that the $R^\pm_d$ observables have no systematic uncertainty from selection efficiency. This is because they are separated by $B$ meson flavour and have the same $D$ meson final state; therefore all efficiencies are assumed to cancel.

Because of the different $B^0$ and $B^0_s$ lifetimes, the ratio of efficiencies for $B^0 \to D(h^+h^-)K^{*0}$ to $B^0_s \to D(h^+h^-)K^{*0}$ is different from one. This ratio is assumed to be equal between all the $D$ meson final states and is calculated using the $B^0 \to D(K^{+}\pi^-)K^{*0}$ and $B^0_s \to D(\pi^+K^-)K^{*0}$ decay modes, assuming that the lifetime difference effects factorise from the other selection effects. The difference in $B^0$ and $B^0_s$ selection efficiencies arises from the use of variables sensitive to the decay topology in the BDT and is equal to 3\%. The systematic uncertainty from this source is labelled “Lifetime difference” in Table 2. The only observables affected by the systematic uncertainty due to lifetime difference are the $R^{hh}_{ds}$ observables, since only these involve both $B$ and $B^0_s$ meson final states and is calculated using the $B^0_s \to D(K^{+}\pi^-)K^{*0}$, $B^0 \to D(K^{+}\pi^-)K^{*0}$, $B^0 \to D(K^+K^-)K^{*0}$ and $B^0 \to D(\pi^+\pi^-)K^{*0}$ decays since it is dependent on the separately optimised selection requirements. The resulting values of $\alpha$ are $0.362 \pm 0.014$, $0.391 \pm 0.014$ and $0.398 \pm 0.014$, respectively. These figures are computed using fully simulated events and data-driven PID efficiencies from calibration samples. The uncertainty on $\alpha$ is propagated to the measured observables to estimate the systematic uncertainty from the production asymmetry and mixing. Owing to the large $B^0_s$ oscillation frequency, a potential production asymmetry of $B^0_s$ mesons does not significantly affect the measurements presented here and is neglected.

4.2 Production asymmetry

The difference between $B^0$ and $\bar{B}^0$, or $B^0_s$ and $\bar{B}^0_s$, production rates in $pp$ collisions is accounted for by applying a correction factor $a_P = (1 - \alpha A_P)/(1 + \alpha A_P)$ to the $\bar{B}^0$ and $\bar{B}^0_s$ signal yields, where

$$A_P = \frac{\sigma(\bar{B}) - \sigma(B)}{\sigma(\bar{B}) + \sigma(B)}$$

(15) is the raw production asymmetry of the $B^0$ or $B^0_s$ mesons in question. In the case of $B^0$ mesons, $A_P$ has been measured, using $B^0 \to J/\psi K^{*0}$ decays, to be $A_P = 0.010 \pm 0.013$ [31]. The effect of the raw production asymmetry on the number of observed $\bar{B}^0$ or $B^0$ decays becomes less pronounced for larger decay times due to mixing. It is also affected by the selection efficiency as a function of the decay time, $\epsilon(B^0 \to DK^{*0}, t)$. A factor, $\alpha$, accounts for this dilution and is given for $B^0$ mesons by

$$\alpha = \frac{\int_0^{+\infty} e^{-t/\tau_B} \cos(\Delta m_d t) \epsilon(B^0 \to DK^{*0}, t) \ dt}{\int_0^{+\infty} e^{-t/\tau_B} \epsilon(B^0 \to DK^{*0}, t) \ dt},$$

(16)

where $\Delta m_d$ is the $B^0$-$\bar{B}^0$ oscillation frequency and $\tau_B$ is the $B^0$ lifetime.

The factor $\alpha$ is evaluated separately for each $B^0 \to D(K^{+}\pi^-)K^{*0}$, $B^0 \to D(K^{+}\pi^-)K^{*0}$ and $B^0 \to D(\pi^+\pi^-)K^{*0}$ decays since it is dependent on the separately optimised selection requirements. The resulting values of $\alpha$ are $0.362 \pm 0.014$, $0.391 \pm 0.014$ and $0.398 \pm 0.014$, respectively. These figures are computed using fully simulated events and data-driven PID efficiencies from calibration samples. The uncertainty on $a_P$ is propagated to the measured observables to estimate the systematic uncertainty from the production asymmetry and mixing. Owing to the large $B^0_s$ oscillation frequency, a potential production asymmetry of $B^0_s$ mesons does not significantly affect the measurements presented here and is neglected.
4.3 Misidentification of D meson decays

Favoured $B^0 \to D(K^+\pi^-)K^{*0}$ decays are misidentified as suppressed $B^0 \to D(\pi^+K^-)K^{*0}$ decays at a small but non-negligible rate. The fraction of signal $B^0 \to D(K^+\pi^-)K^{*0}$ decays reconstructed as signal $B^0 \to D(\pi^+K^-)K^{*0}$ decays is estimated from the simulation to be less than 1% after applying the veto described in Sect. 2. However, the best-fit values of the numbers of $B^0 \to D(\pi^+K^-)K^{*0}$ decays are corrected to take this into account. The uncertainty in this correction causes a systematic uncertainty in the $R_\Delta$ observables given in Table 2 as misID.

4.4 Other corrections

Two ratios of $D^0$ meson decay branching fractions (BF) are needed to compute the final results because of the approximation made between $R_{CP}$ and $R_{hh}$ in Eq. (6). These are taken from Ref. [10], the results of which imply that the ratio of $B(D^0 \to K^-\pi^+)$ to $B(D^0 \to K^+\pi^-)$ is $9.80 \pm 0.24$ and the ratio of $B(D^0 \to K^-\pi^+)$ to $B(D^0 \to \pi^+\pi^-)$ is $27.7 \pm 0.6$.

The fraction of $b$ quarks that hadronize into $B^0$ and $B^0_s$ mesons in $pp$ collisions, $f_d$ and $f_s$, respectively, has an effect on the number of $B^0$ and $B^0_s$ mesons produced in LHCb. Since the $R_{dh}$ observables are ratios of $B^0$ and $B^0_s$ decay partial widths, they are corrected with the hadronisation fraction ratio $f_s/f_d = 0.267 \pm 0.021$ [32]. The $R_{dh}$ observables also contain a factor of $\tau_{B^0_s}/\tau_{B^0}$, which arises because of the lifetimes, $\tau$, of the $B^0$ and $B^0_s$ mesons. This is taken from Ref. [10], the results of which imply that $\tau_{B^0_s}/\tau_{B^0} = 0.99 \pm 0.01$.

4.5 Model-related systematic uncertainty

The $B$ meson invariant mass model is validated with an ensemble of simulated pseudo-experiments. The results of these pseudoexperiments show small biases, of the order of 1% of the statistical uncertainty, in the best-fit values of the signal yields, as determined by the invariant mass fit. The affected signal yields are corrected for these biases before computing the observables. The statistical uncertainty on the bias due to the limited number of pseudoexperiments causes systematic uncertainty in the observables.

Systematic uncertainties due to the effects of the constraints made when constructing the invariant mass fit model are also evaluated with pseudoexperiments. The constraints considered are

1. The values fixed from simulation of the core fraction and the ratio between the widths of the two Gaussian functions used as signal PDF;
2. The difference in mass of the $B^0$ and $B^0_s$ mesons from Ref. [10];
3. The branching ratios from Ref. [10] and selection efficiencies from simulation used to constrain the relative normalisations of the background PDFs.
Table 2: Uncertainties in the observables. All model-related systematic uncertainties are added in quadrature and the result is shown as one source of systematic uncertainty. The presence of ‘–’ indicates that the source of uncertainty does not affect the observable.

</table>

Each fixed parameter of the model has an associated uncertainty. To evaluate this, the invariant mass model is altered such that a particular fixed parameter is varied by its uncertainty and data sets generated with the default model are fitted with this altered value. The variations in the best-fit values of the signal yields observed when changing the model are used to assign a systematic uncertainty on the signal yields. This process is repeated for each fixed parameter and the systematic uncertainties in the signal yields are propagated to the observables. All model-related systematic uncertainties are added in quadrature and this figure is given in Table 2.

5 Results

The results are...
\[ A_d^{KK} = -0.20 \pm 0.15 \pm 0.02, \quad A_d^{\pi\pi} = -0.09 \pm 0.22 \pm 0.02, \]
\[ R_d^{KK} = 1.05^{+0.17}_{-0.15} \pm 0.04, \quad R_d^{\pi\pi} = 1.21^{+0.28}_{-0.25} \pm 0.05, \]
\[ R_d^+ = 0.06 \pm 0.03 \pm 0.01, \quad R_d^- = 0.06 \pm 0.03 \pm 0.01, \]
\[ R_{ds}^{KK} = 0.10 \pm 0.02 \pm 0.01, \quad R_{ds}^{\pi\pi} = 0.15 \pm 0.04 \pm 0.01, \]
\[ A_s^{KK} = -0.04 \pm 0.07 \pm 0.02, \quad A_s^{\pi\pi} = 0.06 \pm 0.13 \pm 0.02, \]
\[ A_d^{K\pi} = -0.03 \pm 0.04 \pm 0.02, \quad A_s^{K\pi} = -0.01 \pm 0.03 \pm 0.02, \]

where the first uncertainties are statistical and the second systematic \cite{33}. The significances of the combined \( B^0 \) and \( \bar{B}^0 \) signals for the \( B^0 \to D(\pi^+ K^-)K^{*0} \), \( \bar{B}^0 \to D(K^+ K^-)K^{*0} \) and \( B^0 \to D(\pi^+ \pi^-)K^{*0} \) decay modes are 2.9\( \sigma \), 8.6\( \sigma \) and 5.8\( \sigma \), respectively, including systematic uncertainties. The statistical significances, expressed in terms of number of standard deviations (\( \sigma \)), are computed from \( \sqrt{2\ln(L_{\text{sig}}/L_0)} \) where \( L_{\text{sig}} \) and \( L_0 \) are the likelihoods from the nominal mass fit described in Sect.\ 3 and from the same fit omitting the signal component, respectively. The likelihoods are convolved with a Gaussian function of width equal to the systematic uncertainties on the fit model in order to compute the total significances. No significant \( CP \) violation effect is observed.

The constraints from the measurements pertaining to \( B^0 \) mesons on the angle \( \gamma \) of the unitarity triangle and the hadronic parameters \( r_B \) and \( \delta_B \) are presented in Sect.\ 6. With more data, improved measurements of the quantities related to \( B_s^0 \to D\bar{K}^{*0} \) decays will also contribute to the sensitivity but are not used here.

### 6 Implication on the value of \( r_B \)

The sensitivity of these results to the CKM phase \( \gamma \) is investigated by employing a frequentist method described in Ref.\ \cite{2} to scan the \( (\gamma, r_B, \delta_B) \) parameter space and calculate the \( \chi^2 \) probability at each point, given the measurements of the observables and using \cite{7}-\cite{11}. The statistical and systematic uncertainties are combined in quadrature and their correlations are accounted for. In principle, the coherence factor \( \kappa \) can also be extracted together with \( \gamma \), \( r_B \) and \( \delta_B \) but the uncertainties of the measurements are too large with the current data sample size to constrain all parameters together. A value of \( \kappa = 0.95 \pm 0.03 \) is used instead. This value is determined from a toy simulation study of a realistic model for the resonance content of \( B^0 \to DK^{+}\pi^- \) decays, similar to the method used in Ref.\ \cite{34}. This model describes the decay amplitude in the analysis phase space as a superposition of a non-resonant component and amplitudes corresponding to the intermediate \( K^*(892)0 \), \( K^*(1410)0 \), \( K_0^*(1430)0 \), \( K_2^*(1430)0 \), \( K^*(1680)0 \), \( D_0^*(2410)^- \), \( D_2^*(2460)^- \) and \( D_{3d}(2573)^+ \) resonances. The relative fractions and phases between these components are generated randomly according to their known values and uncertainties \cite{10} when they have been observed or within conservatively large ranges when they have not been measured. The analysis selection effects are taken into account, and the main
requirements affecting the value of $\kappa$ are the $K^*(892)^0$ mass selection of 50 MeV/$c^2$ around the known mass and the selection on $|\cos \theta^*|$ being larger than 0.4. The $D^0 \to K^{\pm} \pi^\mp$ amplitude ratio $r_D$ and strong phase difference $\delta_D$ are taken from the Heavy Flavour Averaging Group [35].

A one-dimensional projection of the $p$-value, or $1 - \text{CL}$, is given in Fig. 5 which shows that $r_B$ is

$$r_B = 0.240^{+0.055}_{-0.048}$$

at a confidence level of 68.3% and is different from 0 with a significance of 2.7$\sigma$. The $p$-value at each point of $r_B$ is computed with simulated pseudoexperiments following a Feldman-Cousins method, where the nuisance parameters are kept at their best-fit values obtained at each point of $r_B$.

Two-dimensional projections of the $p$-value from the profile likelihood are shown in Fig. 6. The LHCb average value for $\gamma$, extracted from a combination of $B^\pm \to DK^\pm$ and $B^\pm \to D\pi^\pm$ analyses [2], is shown with its 68.3% confidence level interval. The precision of the current results does not allow a significant measurement of $\gamma$ from $B^0 \to DK^{*0}$ decays alone, but these measurements could nonetheless be used in a global fit.

![Figure 5](image)

Figure 5: $p$-value as a function of $r_B$, for $\kappa = 0.95 \pm 0.03$. The horizontal dashed lines represent the 1$\sigma$ and 2$\sigma$ confidence levels and the vertical dotted line represents the obtained central value.

### 7 Conclusions

The parameters of the $B^0 \to DK^{*0}$ decay, which are sensitive to the CKM angle $\gamma$, have been measured with a sample of 3.0 fb$^{-1}$ of LHC $pp$ collision data collected by the LHCb
Figure 6: Two-dimensional projections of the p-value in \((r_B, \delta_B, \gamma)\) parameter space onto (left) \(r_B\) and \(\gamma\) and (right) \(\delta_B\) and \(\gamma\), for \(\kappa = 0.95 \pm 0.03\). The contours are the \(n\)\(\sigma\) profile likelihood contours, where \(\Delta \chi^2 = n^2\) with \(n = 1\) (black), 2 (medium grey), and 3 (light gray), corresponding to 39.4\%, 86.5\% and 98.9\% confidence level, respectively. The vertical line and hashed band represent the best-fit value of \(\gamma\) and the 68.3\% confidence level interval by Ref. [2].

detector. The results include the first measurements of \(CP\) asymmetries in \(B^0\) and \(\bar{B}^0\) to \(DK^{*0}\) decays with the neutral \(D\) meson decaying into the \(\pi^+\pi^-\) final state. The results related to the \(K^+K^-\) final state of the \(D\) meson, \(A_d^{KK}\) and \(R_d^{KK}\), are in agreement with and more precise than those from a previous analysis of LHCb data [36], and supersede them. The measurements of \(R_d^+\) and \(R_d^-\) presented here are the first obtained separately for \(B^0\) and \(\bar{B}^0\) mesons. They are consistent with the measurement of the flavour-averaged ratio

\[
\frac{\Gamma(B^0 \rightarrow D(K^-\pi^+)K^{*0}) + \Gamma(B^0 \rightarrow D(\pi^+K^-)K^{*0})}{\Gamma(B^0 \rightarrow D(K^-\pi^+)K^{*0}) + \Gamma(B^0 \rightarrow D(\pi^+K^-)K^{*0})}
\]

by the Belle collaboration [37] using the same \(K^{*0}\) invariant mass range.

From the measurements presented in this article, we measure the value of \(r_B(DK^{*0})\), the ratio of the amplitudes of the decay \(B^0 \rightarrow DK^{+}\pi^-\) with a \(b \rightarrow u\) or a \(b \rightarrow c\) transition, in a \(K\pi\) mass region of \(\pm 50\) MeV/c\(^2\) around the \(K^{*}(892)^0\) mass, and for an absolute value of the cosine of the \(K^{*0}\) helicity angle larger than 0.4. It is found to be equal to \(0.240^{+0.055}_{-0.048}\) at a confidence level of 68.3\%. This is the first measurement of this parameter with LHCb data and is more accurate than the previous measurement made by the BaBar collaboration [38], in a comparable region of phase space.

Acknowledgements

We express our gratitude to our colleagues in the CERN accelerator departments for the excellent performance of the LHC. We thank the technical and administrative staff at the LHCb institutes. We acknowledge support from CERN and from the national agencies: CAPES, CNPq, FAPERJ and FINEP (Brazil); NSFC (China); CNRS/IN2P3 (France);
